The RTEMS Project is hosted at <http://www.rtems.com>. Any inquiries concerning RTEMS, its related support components, its documentation, or any custom services for RTEMS should be directed to the contacts listed on that site. A current list of RTEMS Support Providers is at <http://www.rtems.com/support.html>.

Table of Contents

List of Figures	1
Preface	3
1 Overview	7
1.1 Introduction	7
1.2 Real-time Application Systems	7
1.3 Real-time Executive	8
1.4 RTEMS Application Architecture	8
1.5 RTEMS Internal Architecture	9
1.6 User Customization and Extensibility	10
1.7 Portability	11
1.8 Memory Requirements	11
1.9 Audience	11
1.10 Conventions	12
1.11 Manual Organization	12
2 Key Concepts	15
2.1 Introduction	15
2.2 Objects	15
2.2.1 Object Names	15
2.2.2 Object IDs	16
2.2.2.1 Thirty-Two Object ID Format	16
2.2.2.2 Sixteen Bit Object ID Format	17
2.2.3 Object ID Description	17
2.3 Communication and Synchronization	18
2.4 Time	18
2.5 Memory Management	19
3 RTEMS Data Types	21
3.1 Introduction	21
3.2 List of Data Types	21
4 Initialization Manager	25
4.1 Introduction	25
4.2 Background	25
4.2.1 Initialization Tasks	25
4.2.2 System Initialization	25
4.2.3 The Idle Task	26
4.2.4 Initialization Manager Failure	26
4.3 Operations	26

4.3.1	Initializing RTEMS	26
4.3.2	Shutting Down RTEMS	27
4.4	Directives	27
4.4.1	INITIALIZE_DATA_STRUCTURES - Initialize RTEMS Data Structures	28
4.4.2	INITIALIZE_BEFORE_DRIVERS - Perform Initialization Before Device Drivers	29
4.4.3	INITIALIZE_DEVICE_DRIVERS - Initialize Device Drivers	30
4.4.4	INITIALIZE_START_MULTITASKING - Complete Initialization and Start Multitasking	31
4.4.5	SHUTDOWN_EXECUTIVE - Shutdown RTEMS	32
5	Task Manager	33
5.1	Introduction	33
5.2	Background	33
5.2.1	Task Definition	33
5.2.2	Task Control Block	34
5.2.3	Task States	34
5.2.4	Task Priority	34
5.2.5	Task Mode	35
5.2.6	Accessing Task Arguments	36
5.2.7	Floating Point Considerations	36
5.2.8	Per Task Variables	37
5.2.9	Building a Task Attribute Set	37
5.2.10	Building a Mode and Mask	38
5.3	Operations	38
5.3.1	Creating Tasks	38
5.3.2	Obtaining Task IDs	39
5.3.3	Starting and Restarting Tasks	39
5.3.4	Suspending and Resuming Tasks	39
5.3.5	Delaying the Currently Executing Task	40
5.3.6	Changing Task Priority	40
5.3.7	Changing Task Mode	40
5.3.8	Notepad Locations	40
5.3.9	Task Deletion	40
5.4	Directives	41
5.4.1	TASK_CREATE - Create a task	42
5.4.2	TASK_IDENT - Get ID of a task	44
5.4.3	TASK_SELF - Obtain ID of caller	45
5.4.4	TASK_START - Start a task	46
5.4.5	TASK_RESTART - Restart a task	47
5.4.6	TASK_DELETE - Delete a task	48
5.4.7	TASK_SUSPEND - Suspend a task	49
5.4.8	TASK_RESUME - Resume a task	50
5.4.9	TASK_IS_SUSPENDED - Determine if a task is Suspended	51
5.4.10	TASK_SET_PRIORITY - Set task priority	52

5.4.11	TASK_MODE - Change the current task mode	53
5.4.12	TASK_GET_NOTE - Get task notepad entry	54
5.4.13	TASK_SET_NOTE - Set task notepad entry	55
5.4.14	TASK_WAKE_AFTER - Wake up after interval	56
5.4.15	TASK_WAKE_WHEN - Wake up when specified	57
5.4.16	ITERATE_OVER_ALL_THREADS - Iterate Over Tasks	58
5.4.17	TASK_VARIABLE_ADD - Associate per task variable...	59
5.4.18	TASK_VARIABLE_GET - Obtain value of a per task variable	60
5.4.19	TASK_VARIABLE_DELETE - Remove per task variable	61
6	Interrupt Manager	63
6.1	Introduction	63
6.2	Background.....	63
6.2.1	Processing an Interrupt	63
6.2.2	RTEMS Interrupt Levels	64
6.2.3	Disabling of Interrupts by RTEMS	64
6.3	Operations.....	64
6.3.1	Establishing an ISR	64
6.3.2	Directives Allowed from an ISR	65
6.4	Directives.....	66
6.4.1	INTERRUPT_CATCH - Establish an ISR	67
6.4.2	INTERRUPT_DISABLE - Disable Interrupts.....	68
6.4.3	INTERRUPT_ENABLE - Enable Interrupts.....	69
6.4.4	INTERRUPT_FLASH - Flash Interrupts	70
6.4.5	INTERRUPT_IS_IN_PROGRESS - Is an ISR in Progress	71
7	Clock Manager	73
7.1	Introduction	73
7.2	Background.....	73
7.2.1	Required Support	73
7.2.2	Time and Date Data Structures	73
7.2.3	Clock Tick and Timeslicing.....	74
7.2.4	Delays	74
7.2.5	Timeouts	74
7.3	Operations.....	74
7.3.1	Announcing a Tick.....	74
7.3.2	Setting the Time	75
7.3.3	Obtaining the Time	75
7.4	Directives.....	75
7.4.1	CLOCK_SET - Set date and time	76
7.4.2	CLOCK_GET - Get date and time information	77
7.4.3	CLOCK_GET_TOD - Get date and time in TOD format..	78
7.4.4	CLOCK_GET_TOD_TIMEVAL - Get date and time in timeval format.....	79

7.4.5	CLOCK_GET_SECONDS_SINCE_EPOCH - Get seconds since epoch	80
7.4.6	CLOCK_GET_TICKS_PER_SECOND - Get ticks per second	81
7.4.7	CLOCK_GET_TICKS_SINCE_BOOT - Get ticks since boot	82
7.4.8	CLOCK_GET_UPTIME - Get the time since boot	83
7.4.9	CLOCK_SET_NANOSECONDS_EXTENSION - Install the nanoseconds since last tick handler	84
7.4.10	CLOCK_TICK - Announce a clock tick	85
8	Timer Manager	87
8.1	Introduction	87
8.2	Background	87
8.2.1	Required Support	87
8.2.2	Timers	87
8.2.3	Timer Server	87
8.2.4	Timer Service Routines	88
8.3	Operations	88
8.3.1	Creating a Timer	88
8.3.2	Obtaining Timer IDs	88
8.3.3	Initiating an Interval Timer	88
8.3.4	Initiating a Time of Day Timer	88
8.3.5	Canceling a Timer	89
8.3.6	Resetting a Timer	89
8.3.7	Initiating the Timer Server	89
8.3.8	Deleting a Timer	89
8.4	Directives	89
8.4.1	TIMER_CREATE - Create a timer	90
8.4.2	TIMER_IDENT - Get ID of a timer	91
8.4.3	TIMER_CANCEL - Cancel a timer	92
8.4.4	TIMER_DELETE - Delete a timer	93
8.4.5	TIMER_FIRE_AFTER - Fire timer after interval	94
8.4.6	TIMER_FIRE_WHEN - Fire timer when specified	95
8.4.7	TIMER_INITIATE_SERVER - Initiate server for task-based timers	96
8.4.8	TIMER_SERVER_FIRE_AFTER - Fire task-based timer after interval	97
8.4.9	TIMER_SERVER_FIRE_WHEN - Fire task-based timer when specified	98
8.4.10	TIMER_RESET - Reset an interval timer	99

9	Semaphore Manager	101
9.1	Introduction	101
9.2	Background	101
9.2.1	Nested Resource Access	101
9.2.2	Priority Inversion	102
9.2.3	Priority Inheritance	102
9.2.4	Priority Ceiling	102
9.2.5	Building a Semaphore Attribute Set	103
9.2.6	Building a SEMAPHORE_OBTAIN Option Set	104
9.3	Operations	105
9.3.1	Creating a Semaphore	105
9.3.2	Obtaining Semaphore IDs	105
9.3.3	Acquiring a Semaphore	105
9.3.4	Releasing a Semaphore	106
9.3.5	Deleting a Semaphore	106
9.4	Directives	106
9.4.1	SEMAPHORE_CREATE - Create a semaphore	107
9.4.2	SEMAPHORE_IDENT - Get ID of a semaphore	109
9.4.3	SEMAPHORE_DELETE - Delete a semaphore	110
9.4.4	SEMAPHORE_OBTAIN - Acquire a semaphore	111
9.4.5	SEMAPHORE_RELEASE - Release a semaphore	113
9.4.6	SEMAPHORE_FLUSH - Unblock all tasks waiting on a semaphore	114
10	Message Manager	115
10.1	Introduction	115
10.2	Background	115
10.2.1	Messages	115
10.2.2	Message Queues	115
10.2.3	Building a Message Queue Attribute Set	115
10.2.4	Building a MESSAGE_QUEUE_RECEIVE Option Set	116
10.3	Operations	116
10.3.1	Creating a Message Queue	116
10.3.2	Obtaining Message Queue IDs	116
10.3.3	Receiving a Message	117
10.3.4	Sending a Message	117
10.3.5	Broadcasting a Message	117
10.3.6	Deleting a Message Queue	117
10.4	Directives	118
10.4.1	MESSAGE_QUEUE_CREATE - Create a queue	119
10.4.2	MESSAGE_QUEUE_IDENT - Get ID of a queue	121
10.4.3	MESSAGE_QUEUE_DELETE - Delete a queue	122
10.4.4	MESSAGE_QUEUE_SEND - Put message at rear of a queue	123
10.4.5	MESSAGE_QUEUE_URGENT - Put message at front of a queue	124
10.4.6	MESSAGE_QUEUE_BROADCAST - Broadcast N messages to a queue	125

10.4.7	MESSAGE_QUEUE_RECEIVE - Receive message from a queue	126
10.4.8	MESSAGE_QUEUE_GET_NUMBER_PENDING - Get number of messages pending on a queue	128
10.4.9	MESSAGE_QUEUE_FLUSH - Flush all messages on a queue	129
11	Event Manager	131
11.1	Introduction	131
11.2	Background	131
11.2.1	Event Sets	131
11.2.2	Building an Event Set or Condition	131
11.2.3	Building an EVENT_RECEIVE Option Set	132
11.3	Operations	132
11.3.1	Sending an Event Set	132
11.3.2	Receiving an Event Set	132
11.3.3	Determining the Pending Event Set	133
11.3.4	Receiving all Pending Events	133
11.4	Directives	133
11.4.1	EVENT_SEND - Send event set to a task	134
11.4.2	EVENT_RECEIVE - Receive event condition	135
12	Signal Manager	137
12.1	Introduction	137
12.2	Background	137
12.2.1	Signal Manager Definitions	137
12.2.2	A Comparison of ASRs and ISRs	137
12.2.3	Building a Signal Set	137
12.2.4	Building an ASR Mode	138
12.3	Operations	138
12.3.1	Establishing an ASR	138
12.3.2	Sending a Signal Set	139
12.3.3	Processing an ASR	139
12.4	Directives	139
12.4.1	SIGNAL_CATCH - Establish an ASR	140
12.4.2	SIGNAL_SEND - Send signal set to a task	141
13	Partition Manager	143
13.1	Introduction	143
13.2	Background	143
13.2.1	Partition Manager Definitions	143
13.2.2	Building a Partition Attribute Set	143
13.3	Operations	143
13.3.1	Creating a Partition	143
13.3.2	Obtaining Partition IDs	144
13.3.3	Acquiring a Buffer	144
13.3.4	Releasing a Buffer	144

13.3.5	Deleting a Partition	144
13.4	Directives	144
13.4.1	PARTITION_CREATE - Create a partition	145
13.4.2	PARTITION_IDENT - Get ID of a partition	147
13.4.3	PARTITION_DELETE - Delete a partition	148
13.4.4	PARTITION_GET_BUFFER - Get buffer from a partition	149
13.4.5	PARTITION_RETURN_BUFFER - Return buffer to a partition	150
14	Region Manager	151
14.1	Introduction	151
14.2	Background	151
14.2.1	Region Manager Definitions	151
14.2.2	Building an Attribute Set	151
14.2.3	Building an Option Set	152
14.3	Operations	152
14.3.1	Creating a Region	152
14.3.2	Obtaining Region IDs	152
14.3.3	Adding Memory to a Region	153
14.3.4	Acquiring a Segment	153
14.3.5	Releasing a Segment	153
14.3.6	Obtaining the Size of a Segment	153
14.3.7	Changing the Size of a Segment	153
14.3.8	Deleting a Region	153
14.4	Directives	154
14.4.1	REGION_CREATE - Create a region	155
14.4.2	REGION_IDENT - Get ID of a region	156
14.4.3	REGION_DELETE - Delete a region	157
14.4.4	REGION_EXTEND - Add memory to a region	158
14.4.5	REGION_GET_SEGMENT - Get segment from a region	159
14.4.6	REGION_RETURN_SEGMENT - Return segment to a region	161
14.4.7	REGION_GET_SEGMENT_SIZE - Obtain size of a segment	162
14.4.8	REGION_RESIZE_SEGMENT - Change size of a segment	163
15	Dual-Ported Memory Manager	165
15.1	Introduction	165
15.2	Background	165
15.3	Operations	165
15.3.1	Creating a Port	165
15.3.2	Obtaining Port IDs	165
15.3.3	Converting an Address	166
15.3.4	Deleting a DPMA Port	166
15.4	Directives	166

15.4.1	PORT_CREATE - Create a port	167
15.4.2	PORT_IDENT - Get ID of a port	168
15.4.3	PORT_DELETE - Delete a port	169
15.4.4	PORT_EXTERNAL_TO_INTERNAL - Convert external to internal address	170
15.4.5	PORT_INTERNAL_TO_EXTERNAL - Convert internal to external address	171
16	I/O Manager	173
16.1	Introduction	173
16.2	Background	173
16.2.1	Device Driver Table	173
16.2.2	Major and Minor Device Numbers	174
16.2.3	Device Names	174
16.2.4	Device Driver Environment	174
16.2.5	Runtime Driver Registration	174
16.2.6	Device Driver Interface	175
16.2.7	Device Driver Initialization	175
16.3	Operations	175
16.3.1	Register and Lookup Name	175
16.3.2	Accessing an Device Driver	175
16.4	Directives	176
16.4.1	IO_REGISTER_DRIVER - Register a device driver	177
16.4.2	IO_UNREGISTER_DRIVER - Unregister a device driver	178
16.4.3	IO_INITIALIZE - Initialize a device driver	179
16.4.4	IO_REGISTER_NAME - Register a device	180
16.4.5	IO_LOOKUP_NAME - Lookup a device	181
16.4.6	IO_OPEN - Open a device	182
16.4.7	IO_CLOSE - Close a device	183
16.4.8	IO_READ - Read from a device	184
16.4.9	IO_WRITE - Write to a device	185
16.4.10	IO_CONTROL - Special device services	186
17	Fatal Error Manager	187
17.1	Introduction	187
17.2	Background	187
17.3	Operations	187
17.3.1	Announcing a Fatal Error	187
17.4	Directives	188
17.4.1	FATAL_ERROR_OCCURRED - Invoke the fatal error handler	189

18	Scheduling Concepts	191
18.1	Introduction	191
18.2	Scheduling Mechanisms	191
18.2.1	Task Priority and Scheduling	191
18.2.2	Preemption	192
18.2.3	Timeslicing	192
18.2.4	Manual Round-Robin	192
18.2.5	Dispatching Tasks	192
18.3	Task State Transitions	193
19	Rate Monotonic Manager	197
19.1	Introduction	197
19.2	Background	197
19.2.1	Rate Monotonic Manager Required Support	197
19.2.2	Period Statistics	197
19.2.3	Rate Monotonic Manager Definitions	198
19.2.4	Rate Monotonic Scheduling Algorithm	199
19.2.5	Schedulability Analysis	200
19.2.5.1	Assumptions	200
19.2.5.2	Processor Utilization Rule	200
19.2.5.3	Processor Utilization Rule Example	200
19.2.5.4	First Deadline Rule	201
19.2.5.5	First Deadline Rule Example	201
19.2.5.6	Relaxation of Assumptions	202
19.2.5.7	Further Reading	202
19.3	Operations	203
19.3.1	Creating a Rate Monotonic Period	203
19.3.2	Manipulating a Period	203
19.3.3	Obtaining the Status of a Period	203
19.3.4	Canceling a Period	204
19.3.5	Deleting a Rate Monotonic Period	204
19.3.6	Examples	204
19.3.7	Simple Periodic Task	204
19.3.8	Task with Multiple Periods	205
19.4	Directives	208
19.4.1	RATE_MONOTONIC_CREATE - Create a rate monotonic period	209
19.4.2	RATE_MONOTONIC_IDENT - Get ID of a period	210
19.4.3	RATE_MONOTONIC_CANCEL - Cancel a period	211
19.4.4	RATE_MONOTONIC_DELETE - Delete a rate monotonic period	212
19.4.5	RATE_MONOTONIC_PERIOD - Conclude current/Start next period	213
19.4.6	RATE_MONOTONIC_GET_STATUS - Obtain status from a period	214
19.4.7	RATE_MONOTONIC_GET_STATISTICS - Obtain statistics from a period	215

19.4.8	RATE_MONOTONIC_RESET_STATISTICS - Reset statistics for a period	216
19.4.9	RATE_MONOTONIC_RESET_ALL_STATISTICS - Reset statistics for all periods	217
19.4.10	RATE_MONOTONIC_REPORT_STATISTICS - Print period statistics report	218
20	Barrier Manager	219
20.1	Introduction	219
20.2	Background	219
20.2.1	Automatic Versus Manual Barriers	219
20.2.2	Building a Barrier Attribute Set	219
20.3	Operations	220
20.3.1	Creating a Barrier	220
20.3.2	Obtaining Barrier IDs	220
20.3.3	Waiting at a Barrier	220
20.3.4	Releasing a Barrier	220
20.3.5	Deleting a Barrier	221
20.4	Directives	221
20.4.1	BARRIER_CREATE - Create a barrier	222
20.4.2	BARRIER_IDENT - Get ID of a barrier	223
20.4.3	BARRIER_DELETE - Delete a barrier	224
20.4.4	BARRIER_OBTAIN - Acquire a barrier	225
20.4.5	BARRIER_RELEASE - Release a barrier	226
21	Board Support Packages	227
21.1	Introduction	227
21.2	Reset and Initialization	227
21.2.1	Interrupt Stack Requirements	228
21.2.2	Processors with a Separate Interrupt Stack	228
21.2.3	Processors Without a Separate Interrupt Stack	228
21.3	Device Drivers	229
21.3.1	Clock Tick Device Driver	229
21.4	User Extensions	229
21.5	Multiprocessor Communications Interface (MPCI)	230
21.5.1	Tightly-Coupled Systems	230
21.5.2	Loosely-Coupled Systems	230
21.5.3	Systems with Mixed Coupling	231
21.5.4	Heterogeneous Systems	231

22	User Extensions Manager	233
22.1	Introduction	233
22.2	Background	233
22.2.1	Extension Sets	233
22.2.2	TCB Extension Area	234
22.2.3	Extensions	235
22.2.3.1	TASK_CREATE Extension	235
22.2.3.2	TASK_START Extension	235
22.2.3.3	TASK_RESTART Extension	236
22.2.3.4	TASK_DELETE Extension	236
22.2.3.5	TASK_SWITCH Extension	236
22.2.3.6	TASK_BEGIN Extension	237
22.2.3.7	TASK_EXITTED Extension	237
22.2.3.8	FATAL Error Extension	237
22.2.4	Order of Invocation	238
22.3	Operations	238
22.3.1	Creating an Extension Set	238
22.3.2	Obtaining Extension Set IDs	238
22.3.3	Deleting an Extension Set	239
22.4	Directives	239
22.4.1	EXTENSION_CREATE - Create a extension set	240
22.4.2	EXTENSION_IDENT - Get ID of a extension set	241
22.4.3	EXTENSION_DELETE - Delete a extension set	242
23	Configuring a System	243
23.1	Introduction	243
23.2	Automatic Generation of System Configuration	243
23.2.1	Library Support Definitions	244
23.2.2	Basic System Information	245
23.2.3	Idle Task Configuration	247
23.2.4	Device Driver Table	247
23.2.5	Multiprocessing Configuration	249
23.2.6	Classic API Configuration	249
23.2.7	Classic API Initialization Tasks Table Configuration	250
23.2.8	POSIX API Configuration	250
23.2.9	POSIX Initialization Threads Table Configuration	251
23.2.10	ITRON API Configuration	251
23.2.11	ITRON Initialization Task Table Configuration	252
23.2.12	Ada Tasks	252
23.2.13	PCI Library	253
23.3	Configuration Table	253
23.4	RTEMS API Configuration Table	257
23.5	POSIX API Configuration Table	260
23.6	CPU Dependent Information Table	263
23.7	Initialization Task Table	263
23.8	Driver Address Table	264
23.9	User Extensions Table	265
23.10	Multiprocessor Configuration Table	267

23.11	Multiprocessor Communications Interface Table	269
23.12	Determining Memory Requirements	270
23.13	Sizing the RTEMS RAM Workspace	271
24	Multiprocessing Manager	275
24.1	Introduction	275
24.2	Background	275
24.2.1	Nodes	275
24.2.2	Global Objects	276
24.2.3	Global Object Table	276
24.2.4	Remote Operations	276
24.2.5	Proxies	277
24.2.6	Multiprocessor Configuration Table	277
24.3	Multiprocessor Communications Interface Layer	278
24.3.1	INITIALIZATION	278
24.3.2	GET_PACKET	279
24.3.3	RETURN_PACKET	279

Preface

In recent years, the cost required to develop a software product has increased significantly while the target hardware costs have decreased. Now a larger portion of money is expended in developing, using, and maintaining software. The trend in computing costs is the complete dominance of software over hardware costs. Because of this, it is necessary that formal disciplines be established to increase the probability that software is characterized by a high degree of correctness, maintainability, and portability. In addition, these disciplines must promote practices that aid in the consistent and orderly development of a software system within schedule and budgetary constraints. To be effective, these disciplines must adopt standards which channel individual software efforts toward a common goal.

The push for standards in the software development field has been met with various degrees of success. The Microprocessor Operating Systems Interfaces (MOSI) effort has experienced only limited success. As popular as the UNIX operating system has grown, the attempt to develop a standard interface definition to allow portable application development has only recently begun to produce the results needed in this area. Unfortunately, very little effort has been expended to provide standards addressing the needs of the real-time community. Several organizations have addressed this need during recent years.

The Real Time Executive Interface Definition (RTEID) was developed by Motorola with technical input from Software Components Group. RTEID was adopted by the VMEbus International Trade Association (VITA) as a baseline draft for their proposed standard multiprocessor, real-time executive interface, Open Real-Time Kernel Interface Definition (ORKID). These two groups are currently working together with the IEEE P1003.4 committee to insure that the functionality of their proposed standards is adopted as the real-time extensions to POSIX.

This emerging standard defines an interface for the development of real-time software to ease the writing of real-time application programs that are directly portable across multiple real-time executive implementations. This interface includes both the source code interfaces and run-time behavior as seen by a real-time application. It does not include the details of how a kernel implements these functions. The standard's goal is to serve as a complete definition of external interfaces so that application code that conforms to these interfaces will execute properly in all real-time executive environments. With the use of a standards compliant executive, routines that acquire memory blocks, create and manage message queues, establish and use semaphores, and send and receive signals need not be redeveloped for a different real-time environment as long as the new environment is compliant with the standard. Software developers need only concentrate on the hardware dependencies of the real-time system. Furthermore, most hardware dependencies for real-time applications can be localized to the device drivers.

A compliant executive provides simple and flexible real-time multiprocessing. It easily lends itself to both tightly-coupled and loosely-coupled configurations (depending on the system hardware configuration). Objects such as tasks, queues, events, signals, semaphores, and memory blocks can be designated as global objects and accessed by any task regardless of which processor the object and the accessing task reside.

The acceptance of a standard for real-time executives will produce the same advantages enjoyed from the push for UNIX standardization by AT&T's System V Interface Definition and IEEE's POSIX efforts. A compliant multiprocessing executive will allow close coupling between UNIX systems and real-time executives to provide the many benefits of the UNIX development environment to be applied to real-time software development. Together they provide the necessary laboratory environment to implement real-time, distributed, embedded systems using a wide variety of computer architectures.

A study was completed in 1988, within the Research, Development, and Engineering Center, U.S. Army Missile Command, which compared the various aspects of the Ada programming language as they related to the application of Ada code in distributed and/or multiple processing systems. Several critical conclusions were derived from the study. These conclusions have a major impact on the way the Army develops application software for embedded applications. These impacts apply to both in-house software development and contractor developed software.

A conclusion of the analysis, which has been previously recognized by other agencies attempting to utilize Ada in a distributed or multiprocessing environment, is that the Ada programming language does not adequately support multiprocessing. Ada does provide a mechanism for multi-tasking, however, this capability exists only for a single processor system. The language also does not have inherent capabilities to access global named variables, flags or program code. These critical features are essential in order for data to be shared between processors. However, these drawbacks do have workarounds which are sometimes awkward and defeat the intent of software maintainability and portability goals.

Another conclusion drawn from the analysis, was that the run time executives being delivered with the Ada compilers were too slow and inefficient to be used in modern missile systems. A run time executive is the core part of the run time system code, or operating system code, that controls task scheduling, input/output management and memory management. Traditionally, whenever efficient executive (also known as kernel) code was required by the application, the user developed in-house software. This software was usually written in assembly language for optimization.

Because of this shortcoming in the Ada programming language, software developers in research and development and contractors for project managed systems, are mandated by technology to purchase and utilize off-the-shelf third party kernel code. The contractor, and eventually the Government, must pay a licensing fee for every copy of the kernel code used in an embedded system.

The main drawback to this development environment is that the Government does not own, nor has the right to modify code contained within the kernel. V&V techniques in this situation are more difficult than if the complete source code were available. Responsibility for system failures due to faulty software is yet another area to be resolved under this environment.

The Guidance and Control Directorate began a software development effort to address these problems. A project to develop an experimental run time kernel was begun that will eliminate the major drawbacks of the Ada programming language mentioned above. The Real Time Executive for Multiprocessor Systems (RTEMS) provides full capabilities for management of tasks, interrupts, time, and multiple processors in addition to those features

typical of generic operating systems. The code is Government owned, so no licensing fees are necessary. RTEMS has been implemented in both the Ada and C programming languages. It has been ported to the following processor families:

- Altera NIOS II
- Analog Devices Blackfin
- Atmel AVR
- ARM
- Freescale (formerly Motorola) MC68xxx
- Freescale (formerly Motorola) MC683xx
- Freescale (formerly Motorola) ColdFire
- Intel i386 and above
- Lattice Semiconductor LM32
- MIPS
- PowerPC
- Renesas (formerly Hitachi) SuperH
- Renesas (formerly Hitachi) H8/300
- Renesas M32C
- Renesas M32R
- SPARC
- Texas Instruments C3x/C4x

Support for other processor families, including RISC, CISC, and DSP, is planned. Since almost all of RTEMS is written in a high level language, ports to additional processor families require minimal effort.

RTEMS multiprocessor support is capable of handling either homogeneous or heterogeneous systems. The kernel automatically compensates for architectural differences (byte swapping, etc.) between processors. This allows a much easier transition from one processor family to another without a major system redesign.

Since the proposed standards are still in draft form, RTEMS cannot and does not claim compliance. However, the status of the standard is being carefully monitored to guarantee that RTEMS provides the functionality specified in the standard. Once approved, RTEMS will be made compliant.

This document is a detailed users guide for a functionally compliant real-time multiprocessor executive. It describes the user interface and run-time behavior of Release 4.10.1 of the C interface to RTEMS.

1 Overview

1.1 Introduction

RTEMS, Real-Time Executive for Multiprocessor Systems, is a real-time executive (kernel) which provides a high performance environment for embedded military applications including the following features:

- multitasking capabilities
- homogeneous and heterogeneous multiprocessor systems
- event-driven, priority-based, preemptive scheduling
- optional rate monotonic scheduling
- intertask communication and synchronization
- priority inheritance
- responsive interrupt management
- dynamic memory allocation
- high level of user configurability

This manual describes the usage of RTEMS for applications written in the C programming language. Those implementation details that are processor dependent are provided in the Applications Supplement documents. A supplement document which addresses specific architectural issues that affect RTEMS is provided for each processor type that is supported.

1.2 Real-time Application Systems

Real-time application systems are a special class of computer applications. They have a complex set of characteristics that distinguish them from other software problems. Generally, they must adhere to more rigorous requirements. The correctness of the system depends not only on the results of computations, but also on the time at which the results are produced. The most important and complex characteristic of real-time application systems is that they must receive and respond to a set of external stimuli within rigid and critical time constraints referred to as deadlines. Systems can be buried by an avalanche of interdependent, asynchronous or cyclical event streams.

Deadlines can be further characterized as either hard or soft based upon the value of the results when produced after the deadline has passed. A deadline is hard if the results have no value or if their use will result in a catastrophic event. In contrast, results which are produced after a soft deadline may have some value.

Another distinguishing requirement of real-time application systems is the ability to coordinate or manage a large number of concurrent activities. Since software is a synchronous entity, this presents special problems. One instruction follows another in a repeating synchronous cycle. Even though mechanisms have been developed to allow for the processing of external asynchronous events, the software design efforts required to process and manage these events and tasks are growing more complicated.

The design process is complicated further by spreading this activity over a set of processors instead of a single processor. The challenges associated with designing and building real-

time application systems become very complex when multiple processors are involved. New requirements such as interprocessor communication channels and global resources that must be shared between competing processors are introduced. The ramifications of multiple processors complicate each and every characteristic of a real-time system.

1.3 Real-time Executive

Fortunately, real-time operating systems or real-time executives serve as a cornerstone on which to build the application system. A real-time multitasking executive allows an application to be cast into a set of logical, autonomous processes or tasks which become quite manageable. Each task is internally synchronous, but different tasks execute independently, resulting in an asynchronous processing stream. Tasks can be dynamically paused for many reasons resulting in a different task being allowed to execute for a period of time. The executive also provides an interface to other system components such as interrupt handlers and device drivers. System components may request the executive to allocate and coordinate resources, and to wait for and trigger synchronizing conditions. The executive system calls effectively extend the CPU instruction set to support efficient multitasking. By causing tasks to travel through well-defined state transitions, system calls permit an application to demand-switch between tasks in response to real-time events.

By proper grouping of responses to stimuli into separate tasks, a system can now asynchronously switch between independent streams of execution, directly responding to external stimuli as they occur. This allows the system design to meet critical performance specifications which are typically measured by guaranteed response time and transaction throughput. The multiprocessor extensions of RTEMS provide the features necessary to manage the extra requirements introduced by a system distributed across several processors. It removes the physical barriers of processor boundaries from the world of the system designer, enabling more critical aspects of the system to receive the required attention. Such a system, based on an efficient real-time, multiprocessor executive, is a more realistic model of the outside world or environment for which it is designed. As a result, the system will always be more logical, efficient, and reliable.

By using the directives provided by RTEMS, the real-time applications developer is freed from the problem of controlling and synchronizing multiple tasks and processors. In addition, one need not develop, test, debug, and document routines to manage memory, pass messages, or provide mutual exclusion. The developer is then able to concentrate solely on the application. By using standard software components, the time and cost required to develop sophisticated real-time applications is significantly reduced.

1.4 RTEMS Application Architecture

One important design goal of RTEMS was to provide a bridge between two critical layers of typical real-time systems. As shown in the following figure, RTEMS serves as a buffer between the project dependent application code and the target hardware. Most hardware dependencies for real-time applications can be localized to the low level device drivers.

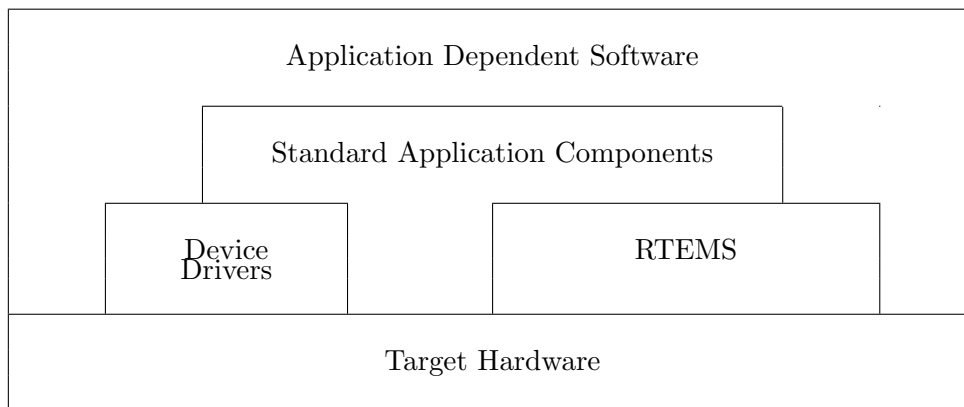

Figure 1.1: RTEMS Application Architecture

The RTEMS I/O interface manager provides an efficient tool for incorporating these hardware dependencies into the system while simultaneously providing a general mechanism to the application code that accesses them. A well designed real-time system can benefit from this architecture by building a rich library of standard application components which can be used repeatedly in other real-time projects.

1.5 RTEMS Internal Architecture

RTEMS can be viewed as a set of layered components that work in harmony to provide a set of services to a real-time application system. The executive interface presented to the application is formed by grouping directives into logical sets called resource managers. Functions utilized by multiple managers such as scheduling, dispatching, and object management are provided in the executive core. The executive core depends on a small set of CPU dependent routines. Together these components provide a powerful run time environment that promotes the development of efficient real-time application systems. The following figure illustrates this organization:

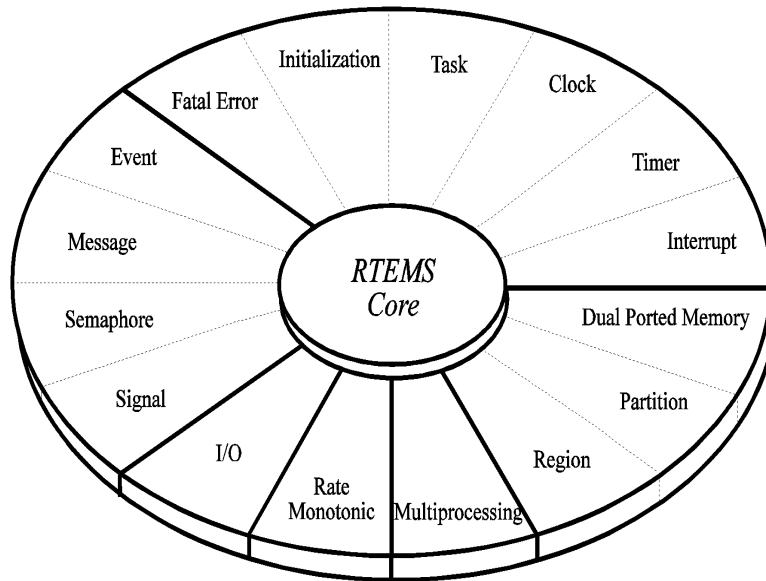

Figure 1.2: RTEMS Layered Architecture

Subsequent chapters present a detailed description of the capabilities provided by each of the following RTEMS managers:

- initialization
- task
- interrupt
- clock
- timer
- semaphore
- message
- event
- signal
- partition
- region
- dual ported memory
- I/O
- fatal error
- rate monotonic
- user extensions
- multiprocessing

1.6 User Customization and Extensibility

As thirty-two bit microprocessors have decreased in cost, they have become increasingly common in a variety of embedded systems. A wide range of custom and general-purpose

processor boards are based on various thirty-two bit processors. RTEMS was designed to make no assumptions concerning the characteristics of individual microprocessor families or of specific support hardware. In addition, RTEMS allows the system developer a high degree of freedom in customizing and extending its features.

RTEMS assumes the existence of a supported microprocessor and sufficient memory for both RTEMS and the real-time application. Board dependent components such as clocks, interrupt controllers, or I/O devices can be easily integrated with RTEMS. The customization and extensibility features allow RTEMS to efficiently support as many environments as possible.

1.7 Portability

The issue of portability was the major factor in the creation of RTEMS. Since RTEMS is designed to isolate the hardware dependencies in the specific board support packages, the real-time application should be easily ported to any other processor. The use of RTEMS allows the development of real-time applications which can be completely independent of a particular microprocessor architecture.

1.8 Memory Requirements

Since memory is a critical resource in many real-time embedded systems, RTEMS was specifically designed to automatically leave out all services that are not required from the run-time environment. Features such as networking, various filesystems, and many other features are completely optional. This allows the application designer the flexibility to tailor RTEMS to most efficiently meet system requirements while still satisfying even the most stringent memory constraints. As a result, the size of the RTEMS executive is application dependent.

RTEMS requires RAM to manage each instance of an RTEMS object that is created. Thus the more RTEMS objects an application needs, the more memory that must be reserved. See [Section 23.12 \[Configuring a System Determining Memory Requirements\]](#), page 270 for more details.

RTEMS utilizes memory for both code and data space. Although RTEMS' data space must be in RAM, its code space can be located in either ROM or RAM.

1.9 Audience

This manual was written for experienced real-time software developers. Although some background is provided, it is assumed that the reader is familiar with the concepts of task management as well as intertask communication and synchronization. Since directives, user related data structures, and examples are presented in C, a basic understanding of the C programming language is required to fully understand the material presented. However, because of the similarity of the Ada and C RTEMS implementations, users will find that the use and behavior of the two implementations is very similar. A working knowledge of the target processor is helpful in understanding some of RTEMS' features. A thorough understanding of the executive cannot be obtained without studying the entire manual because many of RTEMS' concepts and features are interrelated. Experienced RTEMS users will find that the manual organization facilitates its use as a reference document.

1.10 Conventions

The following conventions are used in this manual:

- Significant words or phrases as well as all directive names are printed in bold type.
- Items in bold capital letters are constants defined by RTEMS. Each language interface provided by RTEMS includes a file containing the standard set of constants, data types, and structure definitions which can be incorporated into the user application.
- A number of type definitions are provided by RTEMS and can be found in `rtems.h`.
- The characters "0x" preceding a number indicates that the number is in hexadecimal format. Any other numbers are assumed to be in decimal format.

1.11 Manual Organization

This first chapter has presented the introductory and background material for the RTEMS executive. The remaining chapters of this manual present a detailed description of RTEMS and the environment, including run time behavior, it creates for the user.

A chapter is dedicated to each manager and provides a detailed discussion of each RTEMS manager and the directives which it provides. The presentation format for each directive includes the following sections:

- Calling sequence
- Directive status codes
- Description
- Notes

The following provides an overview of the remainder of this manual:

Chapter 2	Key Concepts: presents an introduction to the ideas which are common across multiple RTEMS managers.
Chapter 3:	RTEMS Data Types: describes the fundamental data types shared by the services in the RTEMS Classic API.
Chapter 4:	Initialization Manager: describes the functionality and directives provided by the Initialization Manager.
Chapter 5:	Task Manager: describes the functionality and directives provided by the Task Manager.
Chapter 6:	Interrupt Manager: describes the functionality and directives provided by the Interrupt Manager.
Chapter 7:	Clock Manager: describes the functionality and directives provided by the Clock Manager.
Chapter 8:	Timer Manager: describes the functionality and directives provided by the Timer Manager.
Chapter 9:	Semaphore Manager: describes the functionality and directives provided by the Semaphore Manager.

Chapter 10:	Message Manager: describes the functionality and directives provided by the Message Manager.
Chapter 11:	Event Manager: describes the functionality and directives provided by the Event Manager.
Chapter 12:	Signal Manager: describes the functionality and directives provided by the Signal Manager.
Chapter 13:	Partition Manager: describes the functionality and directives provided by the Partition Manager.
Chapter 14:	Region Manager: describes the functionality and directives provided by the Region Manager.
Chapter 15:	Dual-Ported Memory Manager: describes the functionality and directives provided by the Dual-Ported Memory Manager.
Chapter 16:	I/O Manager: describes the functionality and directives provided by the I/O Manager.
Chapter 17:	Fatal Error Manager: describes the functionality and directives provided by the Fatal Error Manager.
Chapter 18:	Scheduling Concepts: details the RTEMS scheduling algorithm and task state transitions.
Chapter 19:	Rate Monotonic Manager: describes the functionality and directives provided by the Rate Monotonic Manager.
Chapter 20:	Board Support Packages: defines the functionality required of user-supplied board support packages.
Chapter 21:	User Extensions: shows the user how to extend RTEMS to incorporate custom features.
Chapter 22:	Configuring a System: details the process by which one tailors RTEMS for a particular single-processor or multiprocessor application.
Chapter 23:	Multiprocessing Manager: presents a conceptual overview of the multiprocessing capabilities provided by RTEMS as well as describing the Multiprocessing Communications Interface Layer and Multiprocessing Manager directives.
Chapter 24:	Directive Status Codes: provides a definition of each of the directive status codes referenced in this manual.
Chapter 25:	Example Application: provides a template for simple RTEMS applications.
Chapter 26:	Glossary: defines terms used throughout this manual.

2 Key Concepts

2.1 Introduction

The facilities provided by RTEMS are built upon a foundation of very powerful concepts. These concepts must be understood before the application developer can efficiently utilize RTEMS. The purpose of this chapter is to familiarize one with these concepts.

2.2 Objects

RTEMS provides directives which can be used to dynamically create, delete, and manipulate a set of predefined object types. These types include tasks, message queues, semaphores, memory regions, memory partitions, timers, ports, and rate monotonic periods. The object-oriented nature of RTEMS encourages the creation of modular applications built upon reusable "building block" routines.

All objects are created on the local node as required by the application and have an RTEMS assigned ID. All objects have a user-assigned name. Although a relationship exists between an object's name and its RTEMS assigned ID, the name and ID are not identical. Object names are completely arbitrary and selected by the user as a meaningful "tag" which may commonly reflect the object's use in the application. Conversely, object IDs are designed to facilitate efficient object manipulation by the executive.

2.2.1 Object Names

An object name is an unsigned thirty-two bit entity associated with the object by the user. The data type `rtems_name` is used to store object names.

Although not required by RTEMS, object names are often composed of four ASCII characters which help identify that object. For example, a task which causes a light to blink might be called "LITE". The `rtems_build_name` routine is provided to build an object name from four ASCII characters. The following example illustrates this:

```
rtems_object_name my_name;

my_name = rtems_build_name( 'L', 'I', 'T', 'E' );
```

However, it is not required that the application use ASCII characters to build object names. For example, if an application requires one-hundred tasks, it would be difficult to assign meaningful ASCII names to each task. A more convenient approach would be to name them the binary values one through one-hundred, respectively.

RTEMS provides a helper routine, `rtems_object_get_name`, which can be used to obtain the name of any RTEMS object using just its ID. This routine attempts to convert the name into a printable string.

The following example illustrates the use of this method to print an object name:

```
#include <rtems.h>
#include <rtems/bspIo.h>
```

```

void print_name(rtems_id id)
{
    char  buffer[10];    /* name assumed to be 10 characters or less */
    char *result;

    result = rtems_object_get_name( id, sizeof(buffer), buffer );
    printk( "ID=0x%08x name=%s\n", id, ((result) ? result : "no name") );
}

```

2.2.2 Object IDs

An object ID is a unique unsigned integer value which uniquely identifies an object instance. Object IDs are passed as arguments to many directives in RTEMS and RTEMS translates the ID to an internal object pointer. The efficient manipulation of object IDs is critical to the performance of RTEMS services. Because of this, there are two object Id formats defined. Each target architecture specifies which format it will use. There is a thirty-two bit format which is used for most of the supported architectures and supports multiprocessor configurations. There is also a simpler sixteen bit format which is appropriate for smaller target architectures and does not support multiprocessor configurations.

2.2.2.1 Thirty-Two Object ID Format

The thirty-two bit format for an object ID is composed of four parts: API, object class, node, and index. The data type `rtems_id` is used to store object IDs.

Bits	Contents
0 – 15	Object Index
16 - 23	Node
24 - 26	API
27 - 31	Class

Figure 2.1: Thirty-Two Bit Object Id

The most significant five bits are the object class. The next three bits indicate the API to which the object class belongs. The next eight bits (16-23) are the number of the node on which this object was created. The node number is always one (1) in a single processor system. The least significant sixteen bits form an identifier within a particular object type. This identifier, called the object index, ranges in value from 1 to the maximum number of objects configured for this object type.

2.2.2.2 Sixteen Bit Object ID Format

The sixteen bit format for an object ID is composed of three parts: API, object class, and index. The data type `rtems_id` is used to store object IDs.

Bits	Contents
0 - 7	Object Index
8 - 10	API
11 - 15	Class

Figure 2.2: Sixteen Bit Object Id

The sixteen-bit format is designed to be as similar as possible to the thirty-two bit format. The differences are limited to the elimination of the node field and reduction of the index field from sixteen-bits to 8-bits. Thus the sixteen bit format only supports up to 255 object instances per API/Class combination and single processor systems. As this format is typically utilized by sixteen-bit processors with limited address space, this is more than enough object instances.

2.2.3 Object ID Description

The components of an object ID make it possible to quickly locate any object in even the most complicated multiprocessor system. Object ID's are associated with an object by RTEMS when the object is created and the corresponding ID is returned by the appropriate object create directive. The object ID is required as input to all directives involving objects, except those which create an object or obtain the ID of an object.

The object identification directives can be used to dynamically obtain a particular object's ID given its name. This mapping is accomplished by searching the name table associated with this object type. If the name is non-unique, then the ID associated with the first occurrence of the name will be returned to the application. Since object IDs are returned when the object is created, the object identification directives are not necessary in a properly designed single processor application.

In addition, services are provided to portably examine the subcomponents of an RTEMS ID. These services are described in detail later in this manual but are prototyped as follows:

```
uint32_t rtems_object_id_get_api( rtems_id );
uint32_t rtems_object_id_get_class( rtems_id );
uint32_t rtems_object_id_get_node( rtems_id );
uint32_t rtems_object_id_get_index( rtems_id );
```

An object control block is a data structure defined by RTEMS which contains the information necessary to manage a particular object type. For efficiency reasons, the format of each object type's control block is different. However, many of the fields are similar in function. The number of each type of control block is application dependent and determined by the values specified in the user's Configuration Table. An object control block is allocated at object create time and freed when the object is deleted. With the exception of user extension routines, object control blocks are not directly manipulated by user applications.

2.3 Communication and Synchronization

In real-time multitasking applications, the ability for cooperating execution threads to communicate and synchronize with each other is imperative. A real-time executive should provide an application with the following capabilities:

- Data transfer between cooperating tasks
- Data transfer between tasks and ISRs
- Synchronization of cooperating tasks
- Synchronization of tasks and ISRs

Most RTEMS managers can be used to provide some form of communication and/or synchronization. However, managers dedicated specifically to communication and synchronization provide well established mechanisms which directly map to the application's varying needs. This level of flexibility allows the application designer to match the features of a particular manager with the complexity of communication and synchronization required. The following managers were specifically designed for communication and synchronization:

- Semaphore
- Message Queue
- Event
- Signal

The semaphore manager supports mutual exclusion involving the synchronization of access to one or more shared user resources. Binary semaphores may utilize the optional priority inheritance algorithm to avoid the problem of priority inversion. The message manager supports both communication and synchronization, while the event manager primarily provides a high performance synchronization mechanism. The signal manager supports only asynchronous communication and is typically used for exception handling.

2.4 Time

The development of responsive real-time applications requires an understanding of how RTEMS maintains and supports time-related operations. The basic unit of time in RTEMS is known as a tick. The frequency of clock ticks is completely application dependent and determines the granularity and accuracy of all interval and calendar time operations.

By tracking time in units of ticks, RTEMS is capable of supporting interval timing functions such as task delays, timeouts, timeslicing, the delayed execution of timer service routines, and the rate monotonic scheduling of tasks. An interval is defined as a number of ticks relative to the current time. For example, when a task delays for an interval of ten ticks,

it is implied that the task will not execute until ten clock ticks have occurred. All intervals are specified using data type `rtems_interval`.

A characteristic of interval timing is that the actual interval period may be a fraction of a tick less than the interval requested. This occurs because the time at which the delay timer is set up occurs at some time between two clock ticks. Therefore, the first countdown tick occurs in less than the complete time interval for a tick. This can be a problem if the clock granularity is large.

The rate monotonic scheduling algorithm is a hard real-time scheduling methodology. This methodology provides rules which allows one to guarantee that a set of independent periodic tasks will always meet their deadlines – even under transient overload conditions. The rate monotonic manager provides directives built upon the Clock Manager’s interval timer support routines.

Interval timing is not sufficient for the many applications which require that time be kept in wall time or true calendar form. Consequently, RTEMS maintains the current date and time. This allows selected time operations to be scheduled at an actual calendar date and time. For example, a task could request to delay until midnight on New Year’s Eve before lowering the ball at Times Square. The data type `rtems_time_of_day` is used to specify calendar time in RTEMS services. See [Section 7.2.2 \[Time and Date Data Structures\]](#), [page 73](#).

Obviously, the directives which use intervals or wall time cannot operate without some external mechanism which provides a periodic clock tick. This clock tick is typically provided by a real time clock or counter/timer device.

2.5 Memory Management

RTEMS memory management facilities can be grouped into two classes: dynamic memory allocation and address translation. Dynamic memory allocation is required by applications whose memory requirements vary through the application’s course of execution. Address translation is needed by applications which share memory with another CPU or an intelligent Input/Output processor. The following RTEMS managers provide facilities to manage memory:

- Region
- Partition
- Dual Ported Memory

RTEMS memory management features allow an application to create simple memory pools of fixed size buffers and/or more complex memory pools of variable size segments. The partition manager provides directives to manage and maintain pools of fixed size entities such as resource control blocks. Alternatively, the region manager provides a more general purpose memory allocation scheme that supports variable size blocks of memory which are dynamically obtained and freed by the application. The dual-ported memory manager provides executive support for address translation between internal and external dual-ported RAM address space.

3 RTEMS Data Types

3.1 Introduction

This chapter contains a complete list of the RTEMS primitive data types in alphabetical order. This is intended to be an overview and the user is encouraged to look at the appropriate chapters in the manual for more information about the usage of the various data types.

3.2 List of Data Types

The following is a complete list of the RTEMS primitive data types in alphabetical order:

- `rtems_address` is the data type used to manage addresses. It is equivalent to a "void *" pointer.
- `rtems_asr` is the return type for an RTEMS ASR.
- `rtems_asr_entry` is the address of the entry point to an RTEMS ASR.
- `rtems_attribute` is the data type used to manage the attributes for RTEMS objects. It is primarily used as an argument to object create routines to specify characteristics of the new object.
- `rtems_boolean` may only take on the values of `TRUE` and `FALSE`.
This type is deprecated. Use "bool" instead.
- `rtems_context` is the CPU dependent data structure used to manage the integer and system register portion of each task's context.
- `rtems_context_fp` is the CPU dependent data structure used to manage the floating point portion of each task's context.
- `rtems_device_driver` is the return type for a RTEMS device driver routine.
- `rtems_device_driver_entry` is the entry point to a RTEMS device driver routine.
- `rtems_device_major_number` is the data type used to manage device major numbers.
- `rtems_device_minor_number` is the data type used to manage device minor numbers.
- `rtems_double` is the RTEMS data type that corresponds to double precision floating point on the target hardware.
This type is deprecated. Use "double" instead.
- `rtems_event_set` is the data type used to manage and manipulate RTEMS event sets with the Event Manager.
- `rtems_extension` is the return type for RTEMS user extension routines.
- `rtems_fatal_extension` is the entry point for a fatal error user extension handler routine.
- `rtems_id` is the data type used to manage and manipulate RTEMS object IDs.
- `rtems_interrupt_frame` is the data structure that defines the format of the interrupt stack frame as it appears to a user ISR. This data structure may not be defined on all ports.

- `rtems_interrupt_level` is the data structure used with the `rtems_interrupt_disable`, `rtems_interrupt_enable`, and `rtems_interrupt_flash` routines. This data type is CPU dependent and usually corresponds to the contents of the processor register containing the interrupt mask level.
- `rtems_interval` is the data type used to manage and manipulate time intervals. Intervals are non-negative integers used to measure the length of time in clock ticks.
- `rtems_isr` is the return type of a function implementing an RTEMS ISR.
- `rtems_isr_entry` is the address of the entry point to an RTEMS ISR. It is equivalent to the entry point of the function implementing the ISR.
- `rtems_mp_packet_classes` is the enumerated type which specifies the categories of multiprocessing messages. For example, one of the classes is for messages that must be processed by the Task Manager.
- `rtems_mode` is the data type used to manage and dynamically manipulate the execution mode of an RTEMS task.
- `rtems_mpci_entry` is the return type of an RTEMS MPCIE routine.
- `rtems_mpci_get_packet_entry` is the address of the entry point to the get packet routine for an MPCIE implementation.
- `rtems_mpci_initialization_entry` is the address of the entry point to the initialization routine for an MPCIE implementation.
- `rtems_mpci_receive_packet_entry` is the address of the entry point to the receive packet routine for an MPCIE implementation.
- `rtems_mpci_return_packet_entry` is the address of the entry point to the return packet routine for an MPCIE implementation.
- `rtems_mpci_send_packet_entry` is the address of the entry point to the send packet routine for an MPCIE implementation.
- `rtems_mpci_table` is the data structure containing the configuration information for an MPCIE.
- `rtems_name` is the data type used to contain the name of a Classic API object. It is an unsigned thirty-two bit integer which can be treated as a numeric value or initialized using `rtems_build_name` to contain four ASCII characters.
- `rtems_option` is the data type used to specify which behavioral options the caller desires. It is commonly used with potentially blocking directives to specify whether the caller is willing to block or return immediately with an error indicating that the resource was not available.
- `rtems_packet_prefix` is the data structure that defines the first bytes in every packet sent between nodes in an RTEMS multiprocessor system. It contains routing information that is expected to be used by the MPCIE layer.
- `rtems_signal_set` is the data type used to manage and manipulate RTEMS signal sets with the Signal Manager.
- `int8_t` is the C99 data type that corresponds to signed eight bit integers. This data type is defined by RTEMS in a manner that ensures it is portable across different target processors.

- `int16_t` is the C99 data type that corresponds to signed sixteen bit integers. This data type is defined by RTEMS in a manner that ensures it is portable across different target processors.
- `int32_t` is the C99 data type that corresponds to signed thirty-two bit integers. This data type is defined by RTEMS in a manner that ensures it is portable across different target processors.
- `int64_t` is the C99 data type that corresponds to signed sixty-four bit integers. This data type is defined by RTEMS in a manner that ensures it is portable across different target processors.
- `rtems_single` is the RTEMS data type that corresponds to single precision floating point on the target hardware.
This type is deprecated. Use "float" instead.
- `rtems_status_codes` is the return type for most RTEMS services. This is an enumerated type of approximately twenty-five values. In general, when a service returns a particular status code, it indicates that a very specific error condition has occurred.
- `rtems_task` is the return type for an RTEMS Task.
- `rtems_task_argument` is the data type for the argument passed to each RTEMS task. In RTEMS 4.7 and older, this is an unsigned thirty-two bit integer. In RTEMS 4.8 and newer, this is based upon the C99 type `uintptr_t` which is guaranteed to be an integer large enough to hold a pointer on the target architecture.
- `rtems_task_begin_extension` is the entry point for a task beginning execution user extension handler routine.
- `rtems_task_create_extension` is the entry point for a task creation execution user extension handler routine.
- `rtems_task_delete_extension` is the entry point for a task deletion user extension handler routine.
- `rtems_task_entry` is the address of the entry point to an RTEMS ASR. It is equivalent to the entry point of the function implementing the ASR.
- `rtems_task_exitted_extension` is the entry point for a task exited user extension handler routine.
- `rtems_task_priority` is the data type used to manage and manipulate task priorities.
- `rtems_task_restart_extension` is the entry point for a task restart user extension handler routine.
- `rtems_task_start_extension` is the entry point for a task start user extension handler routine.
- `rtems_task_switch_extension` is the entry point for a task context switch user extension handler routine.
- `rtems_tcb` is the data structure associated with each task in an RTEMS system.
- `rtems_time_of_day` is the data structure used to manage and manipulate calendar time in RTEMS.
- `rtems_timer_service_routine` is the return type for an RTEMS Timer Service Routine.

- `rtems_timer_service_routine_entry` is the address of the entry point to an RTEMS TSR. It is equivalent to the entry point of the function implementing the TSR.
- `rtems_vector_number` is the data type used to manage and manipulate interrupt vector numbers.
- `uint8_t` is the C99 data type that corresponds to unsigned eight bit integers. This data type is defined by RTEMS in a manner that ensures it is portable across different target processors.
- `uint16_t` is the C99 data type that corresponds to unsigned sixteen bit integers. This data type is defined by RTEMS in a manner that ensures it is portable across different target processors.
- `uint32_t` is the C99 data type that corresponds to unsigned thirty-two bit integers. This data type is defined by RTEMS in a manner that ensures it is portable across different target processors.
- `uint64_t` is the C99 data type that corresponds to unsigned sixty-four bit integers. This data type is defined by RTEMS in a manner that ensures it is portable across different target processors.
- `uintptr_t` is the C99 data type that corresponds to the unsigned integer type that is of sufficient size to represent addresses as unsigned integers. This data type is defined by RTEMS in a manner that ensures it is portable across different target processors.

4 Initialization Manager

4.1 Introduction

The Initialization Manager is responsible for initiating and shutting down RTEMS. Initiating RTEMS involves creating and starting all configured initialization tasks, and for invoking the initialization routine for each user-supplied device driver. In a multiprocessor configuration, this manager also initializes the interprocessor communications layer. The directives provided by the Initialization Manager are:

- `rtems_initialize_data_structures` - Initialize RTEMS Data Structures
- `rtems_initialize_before_drivers` - Perform Initialization Before Device Drivers
- `rtems_initialize_device_drivers` - Initialize Device Drivers
- `rtems_initialize_start_multitasking` - Complete Initialization and Start Multitasking
- `rtems_shutdown_executive` - Shutdown RTEMS

4.2 Background

4.2.1 Initialization Tasks

Initialization task(s) are the mechanism by which RTEMS transfers initial control to the user's application. Initialization tasks differ from other application tasks in that they are defined in the User Initialization Tasks Table and automatically created and started by RTEMS as part of its initialization sequence. Since the initialization tasks are scheduled using the same algorithm as all other RTEMS tasks, they must be configured at a priority and mode which will ensure that they will complete execution before other application tasks execute. Although there is no upper limit on the number of initialization tasks, an application is required to define at least one.

A typical initialization task will create and start the static set of application tasks. It may also create any other objects used by the application. Initialization tasks which only perform initialization should delete themselves upon completion to free resources for other tasks. Initialization tasks may transform themselves into a "normal" application task. This transformation typically involves changing priority and execution mode. RTEMS does not automatically delete the initialization tasks.

4.2.2 System Initialization

System Initialization begins with board reset and continues through RTEMS initialization, initialization of all device drivers, and eventually a context switch to the first user task. Remember, that interrupts are disabled during initialization and the *initialization thread* is not a task in any sense and the user should be very careful during initialization.

The BSP must ensure that there is enough stack space reserved for the initialization "thread" to successfully execute the initialization routines for all device drivers and, in multiprocessor configurations, the Multiprocessor Communications Interface Layer initialization routine.

4.2.3 The Idle Task

The Idle Task is the lowest priority task in a system and executes only when no other task is ready to execute. This default implementation of this task consists of an infinite loop. RTEMS allows the Idle Task body to be replaced by a CPU specific implementation, a BSP specific implementation or an application specific implementation.

The Idle Task is preemptible and **WILL** be preempted when any other task is made ready to execute. This characteristic is critical to the overall behavior of any application.

4.2.4 Initialization Manager Failure

The `rtems_fatal_error_occurred` directive will be invoked from `rtems_initialize_executive` for any of the following reasons:

- If either the Configuration Table or the CPU Dependent Information Table is not provided.
- If the starting address of the RTEMS RAM Workspace, supplied by the application in the Configuration Table, is NULL or is not aligned on a four-byte boundary.
- If the size of the RTEMS RAM Workspace is not large enough to initialize and configure the system.
- If the interrupt stack size specified is too small.
- If multiprocessing is configured and the node entry in the Multiprocessor Configuration Table is not between one and the `maximum_nodes` entry.
- If a multiprocessor system is being configured and no Multiprocessor Communications Interface is specified.
- If no user initialization tasks are configured. At least one initialization task must be configured to allow RTEMS to pass control to the application at the end of the executive initialization sequence.
- If any of the user initialization tasks cannot be created or started successfully.

A discussion of RTEMS actions when a fatal error occurs may be found [Section 17.3.1 \[Fatal Error Manager Announcing a Fatal Error\]](#), page 187.

4.3 Operations

4.3.1 Initializing RTEMS

The Initialization Manager directives are called by the Board Support Package framework as part of its initialization sequence. RTEMS assumes that the Board Support Package successfully completed its initialization activities. These directives initialize RTEMS by performing the following actions:

- Initializing internal RTEMS variables;
- Allocating system resources;
- Creating and starting the Idle Task;
- Initialize all device drivers;
- Creating and starting the user initialization task(s); and

- Initiating multitasking.

The initialization directives **MUST** be called in the proper sequence before any blocking directives may be used. The services in this manager should be invoked just once per application and in precisely the following order:

- `rtems_initialize_data_structures`
- `rtems_initialize_before_drivers`
- `rtems_initialize_device_drivers`
- `rtems_initialize_start_multitasking`

It is recommended that the Board Support Package use the provided framework which will invoke these services as part of the executing the function `boot_card` in the file `c/src/lib/libbsp/shared/bootcard.c`. This framework will also assist in allocating memory to the RTEMS Workspace and C Program Heap and initializing the C Library.

The effect of calling any blocking RTEMS directives before `rtems_initialize_start_multitasking` is unpredictable but guaranteed to be bad. After the directive `rtems_initialize_data_structures` is invoked, it is permissible to allocate RTEMS objects and perform non-blocking operations. But the user should be distinctly aware that multitasking is not available yet and they are **NOT** executing in a task context.

Many of RTEMS actions during initialization are based upon the contents of the Configuration Table. For more information regarding the format and contents of this table, please refer to the chapter [Chapter 23 \[Configuring a System\]](#), page 243.

The final step in the initialization sequence is the initiation of multitasking. When the scheduler and dispatcher are enabled, the highest priority, ready task will be dispatched to run. Control will not be returned to the Board Support Package after multitasking is enabled until the `rtems_shutdown_executive` directive is called. This directive is called as a side-effect of POSIX calls including `exit`.

4.3.2 Shutting Down RTEMS

The `rtems_shutdown_executive` directive is invoked by the application to end multitasking and return control to the board support package. The board support package resumes execution at the code immediately following the invocation of the `rtems_initialize_start_multitasking` directive.

4.4 Directives

This section details the Initialization Manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

4.4.1 INITIALIZE_DATA_STRUCTURES - Initialize RTEMS Data Structures

CALLING SEQUENCE:

```
void rtems_initialize_data_structures(void);
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive is called when the Board Support Package has completed its basic initialization and allows RTEMS to initialize the application environment based upon the information in the Configuration Table, User Initialization Tasks Table, Device Driver Table, User Extension Table, Multiprocessor Configuration Table, and the Multiprocessor Communications Interface (MPCI) Table. This directive returns to the caller after completing the basic RTEMS initialization.

NOTES:

The Initialization Manager directives must be used in the proper sequence and invoked only once in the life of an application.

This directive must be invoked with interrupts disabled. Interrupts should be disabled as early as possible in the initialization sequence and remain disabled until the first context switch.

4.4.2 INITIALIZE_BEFORE_DRIVERS - Perform Initialization Before Device Drivers

CALLING SEQUENCE:

```
void rtems_initialize_before_drivers(void);
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive is called by the Board Support Package as the second step in initializing RTEMS. This directive performs initialization that must occur between basic RTEMS data structure initialization and device driver initialization. In particular, in a multiprocessor configuration, this directive will create the MPCIE Server Task. This directive returns to the caller after completing the basic RTEMS initialization.

NOTES:

The Initialization Manager directives must be used in the proper sequence and invoked only once in the life of an application.

This directive must be invoked with interrupts disabled. Interrupts should be disabled as early as possible in the initialization sequence and remain disabled until the first context switch.

4.4.3 INITIALIZE_DEVICE_DRIVERS - Initialize Device Drivers CALLING SEQUENCE:

```
void rtems_initialize_device_drivers(void);
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive is called by the Board Support Package as the third step in initializing RTEMS. This directive initializes all statically configured device drivers and performs all RTEMS initialization which requires device drivers to be initialized.

In a multiprocessor configuration, this service will initialize the Multiprocessor Communications Interface (MPCI) and synchronize with the other nodes in the system.

After this directive is executed, control will be returned to the Board Support Package framework.

NOTES:

The Initialization Manager directives must be used in the proper sequence and invoked only once in the life of an application.

This directive must be invoked with interrupts disabled. Interrupts should be disabled as early as possible in the initialization sequence and remain disabled until the first context switch.

4.4.4 INITIALIZE_START_MULTITASKING - Complete Initialization and Start Multitasking

CALLING SEQUENCE:

```
void rtems_initialize_start_multitasking(void);
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive is called after the other Initialization Manager directives have successfully completed. This directive initiates multitasking and performs a context switch to the first user application task and enables interrupts as a side-effect of that context switch.

NOTES:

This directive **DOES NOT RETURN** to the caller until the `rtems_shutdown_executive` is invoked.

This directive causes all nodes in the system to verify that certain configuration parameters are the same as those of the local node. If an inconsistency is detected, then a fatal error is generated.

4.4.5 SHUTDOWN_EXECUTIVE - Shutdown RTEMS

CALLING SEQUENCE:

```
void rtems_shutdown_executive(  
    uint32_t result  
);
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive is called when the application wishes to shutdown RTEMS and return control to the board support package. The board support package resumes execution at the code immediately following the invocation of the `rtems_initialize_executive` directive.

NOTES:

This directive **MUST** be the last RTEMS directive invoked by an application and it **DOES NOT RETURN** to the caller.

This directive should not be invoked until the executive has successfully completed initialization.

5 Task Manager

5.1 Introduction

The task manager provides a comprehensive set of directives to create, delete, and administer tasks. The directives provided by the task manager are:

- `rtems_task_create` - Create a task
- `rtems_task_ident` - Get ID of a task
- `rtems_task_self` - Obtain ID of caller
- `rtems_task_start` - Start a task
- `rtems_task_restart` - Restart a task
- `rtems_task_delete` - Delete a task
- `rtems_task_suspend` - Suspend a task
- `rtems_task_resume` - Resume a task
- `rtems_task_is_suspended` - Determine if a task is suspended
- `rtems_task_set_priority` - Set task priority
- `rtems_task_mode` - Change current task's mode
- `rtems_task_get_note` - Get task notepad entry
- `rtems_task_set_note` - Set task notepad entry
- `rtems_task_wake_after` - Wake up after interval
- `rtems_task_wake_when` - Wake up when specified
- `rtems_iterate_over_all_threads` - Iterate Over Tasks
- `rtems_task_variable_add` - Associate per task variable
- `rtems_task_variable_get` - Obtain value of a a per task variable
- `rtems_task_variable_delete` - Remove per task variable

5.2 Background

5.2.1 Task Definition

Many definitions of a task have been proposed in computer literature. Unfortunately, none of these definitions encompasses all facets of the concept in a manner which is operating system independent. Several of the more common definitions are provided to enable each user to select a definition which best matches their own experience and understanding of the task concept:

- a "dispatchable" unit.
- an entity to which the processor is allocated.
- an atomic unit of a real-time, multiprocessor system.
- single threads of execution which concurrently compete for resources.
- a sequence of closely related computations which can execute concurrently with other computational sequences.

From RTEMS' perspective, a task is the smallest thread of execution which can compete on its own for system resources. A task is manifested by the existence of a task control block (TCB).

5.2.2 Task Control Block

The Task Control Block (TCB) is an RTEMS defined data structure which contains all the information that is pertinent to the execution of a task. During system initialization, RTEMS reserves a TCB for each task configured. A TCB is allocated upon creation of the task and is returned to the TCB free list upon deletion of the task.

The TCB's elements are modified as a result of system calls made by the application in response to external and internal stimuli. TCBs are the only RTEMS internal data structure that can be accessed by an application via user extension routines. The TCB contains a task's name, ID, current priority, current and starting states, execution mode, set of notepad locations, TCB user extension pointer, scheduling control structures, as well as data required by a blocked task.

A task's context is stored in the TCB when a task switch occurs. When the task regains control of the processor, its context is restored from the TCB. When a task is restarted, the initial state of the task is restored from the starting context area in the task's TCB.

5.2.3 Task States

A task may exist in one of the following five states:

- **executing** - Currently scheduled to the CPU
- **ready** - May be scheduled to the CPU
- **blocked** - Unable to be scheduled to the CPU
- **dormant** - Created task that is not started
- **non-existent** - Uncreated or deleted task

An active task may occupy the executing, ready, blocked or dormant state, otherwise the task is considered non-existent. One or more tasks may be active in the system simultaneously. Multiple tasks communicate, synchronize, and compete for system resources with each other via system calls. The multiple tasks appear to execute in parallel, but actually each is dispatched to the CPU for periods of time determined by the RTEMS scheduling algorithm. The scheduling of a task is based on its current state and priority.

5.2.4 Task Priority

A task's priority determines its importance in relation to the other tasks executing on the same processor. RTEMS supports 255 levels of priority ranging from 1 to 255. The data type `rtems_task_priority` is used to store task priorities.

Tasks of numerically smaller priority values are more important tasks than tasks of numerically larger priority values. For example, a task at priority level 5 is of higher privilege than a task at priority level 10. There is no limit to the number of tasks assigned to the same priority.

Each task has a priority associated with it at all times. The initial value of this priority is assigned at task creation time. The priority of a task may be changed at any subsequent time.

Priorities are used by the scheduler to determine which ready task will be allowed to execute. In general, the higher the logical priority of a task, the more likely it is to receive processor execution time.

5.2.5 Task Mode

A task's execution mode is a combination of the following four components:

- preemption
- ASR processing
- timeslicing
- interrupt level

It is used to modify RTEMS' scheduling process and to alter the execution environment of the task. The data type `rtems_task_mode` is used to manage the task execution mode.

The preemption component allows a task to determine when control of the processor is relinquished. If preemption is disabled (`RTEMS_NO_PREEMPT`), the task will retain control of the processor as long as it is in the executing state – even if a higher priority task is made ready. If preemption is enabled (`RTEMS_PREEMPT`) and a higher priority task is made ready, then the processor will be taken away from the current task immediately and given to the higher priority task.

The timeslicing component is used by the RTEMS scheduler to determine how the processor is allocated to tasks of equal priority. If timeslicing is enabled (`RTEMS_TIMESLICE`), then RTEMS will limit the amount of time the task can execute before the processor is allocated to another ready task of equal priority. The length of the timeslice is application dependent and specified in the Configuration Table. If timeslicing is disabled (`RTEMS_NO_TIMESLICE`), then the task will be allowed to execute until a task of higher priority is made ready. If `RTEMS_NO_PREEMPT` is selected, then the timeslicing component is ignored by the scheduler.

The asynchronous signal processing component is used to determine when received signals are to be processed by the task. If signal processing is enabled (`RTEMS_ASR`), then signals sent to the task will be processed the next time the task executes. If signal processing is disabled (`RTEMS_NO_ASR`), then all signals received by the task will remain posted until signal processing is enabled. This component affects only tasks which have established a routine to process asynchronous signals.

The interrupt level component is used to determine which interrupts will be enabled when the task is executing. `RTEMS_INTERRUPT_LEVEL(n)` specifies that the task will execute at interrupt level `n`.

- `RTEMS_PREEMPT` - enable preemption (default)
- `RTEMS_NO_PREEMPT` - disable preemption
- `RTEMS_NO_TIMESLICE` - disable timeslicing (default)
- `RTEMS_TIMESLICE` - enable timeslicing

- RTEMS_ASR - enable ASR processing (default)
- RTEMS_NO_ASR - disable ASR processing
- RTEMS_INTERRUPT_LEVEL(0) - enable all interrupts (default)
- RTEMS_INTERRUPT_LEVEL(n) - execute at interrupt level n

The set of default modes may be selected by specifying the RTEMS_DEFAULT_MODES constant.

5.2.6 Accessing Task Arguments

All RTEMS tasks are invoked with a single argument which is specified when they are started or restarted. The argument is commonly used to communicate startup information to the task. The simplest manner in which to define a task which accesses its argument is:

```
rtems_task user_task(
    rtems_task_argument argument
);
```

Application tasks requiring more information may view this single argument as an index into an array of parameter blocks.

5.2.7 Floating Point Considerations

Creating a task with the RTEMS_FLOATING_POINT attribute flag results in additional memory being allocated for the TCB to store the state of the numeric coprocessor during task switches. This additional memory is **NOT** allocated for RTEMS_NO_FLOATING_POINT tasks. Saving and restoring the context of a RTEMS_FLOATING_POINT task takes longer than that of a RTEMS_NO_FLOATING_POINT task because of the relatively large amount of time required for the numeric coprocessor to save or restore its computational state.

Since RTEMS was designed specifically for embedded military applications which are floating point intensive, the executive is optimized to avoid unnecessarily saving and restoring the state of the numeric coprocessor. The state of the numeric coprocessor is only saved when a RTEMS_FLOATING_POINT task is dispatched and that task was not the last task to utilize the coprocessor. In a system with only one RTEMS_FLOATING_POINT task, the state of the numeric coprocessor will never be saved or restored.

Although the overhead imposed by RTEMS_FLOATING_POINT tasks is minimal, some applications may wish to completely avoid the overhead associated with RTEMS_FLOATING_POINT tasks and still utilize a numeric coprocessor. By preventing a task from being preempted while performing a sequence of floating point operations, a RTEMS_NO_FLOATING_POINT task can utilize the numeric coprocessor without incurring the overhead of a RTEMS_FLOATING_POINT context switch. This approach also avoids the allocation of a floating point context area. However, if this approach is taken by the application designer, NO tasks should be created as RTEMS_FLOATING_POINT tasks. Otherwise, the floating point context will not be correctly maintained because RTEMS assumes that the state of the numeric coprocessor will not be altered by RTEMS_NO_FLOATING_POINT tasks.

If the supported processor type does not have hardware floating capabilities or a standard numeric coprocessor, RTEMS will not provide built-in support for hardware floating point on that processor. In this case, all tasks are considered RTEMS_NO_FLOATING_POINT whether

created as `RTEMS_FLOATING_POINT` or `RTEMS_NO_FLOATING_POINT` tasks. A floating point emulation software library must be utilized for floating point operations.

On some processors, it is possible to disable the floating point unit dynamically. If this capability is supported by the target processor, then RTEMS will utilize this capability to enable the floating point unit only for tasks which are created with the `RTEMS_FLOATING_POINT` attribute. The consequence of a `RTEMS_NO_FLOATING_POINT` task attempting to access the floating point unit is CPU dependent but will generally result in an exception condition.

5.2.8 Per Task Variables

Per task variables are used to support global variables whose value may be unique to a task. After indicating that a variable should be treated as private (i.e. per-task) the task can access and modify the variable, but the modifications will not appear to other tasks, and other tasks' modifications to that variable will not affect the value seen by the task. This is accomplished by saving and restoring the variable's value each time a task switch occurs to or from the calling task.

The value seen by other tasks, including those which have not added the variable to their set and are thus accessing the variable as a common location shared among tasks, can not be affected by a task once it has added a variable to its local set. Changes made to the variable by other tasks will not affect the value seen by a task which has added the variable to its private set.

This feature can be used when a routine is to be spawned repeatedly as several independent tasks. Although each task will have its own stack, and thus separate stack variables, they will all share the same static and global variables. To make a variable not shareable (i.e. a "global" variable that is specific to a single task), the tasks can call `rtems_task_variable_add` to make a separate copy of the variable for each task, but all at the same physical address.

Task variables increase the context switch time to and from the tasks that own them so it is desirable to minimize the number of task variables. One efficient method is to have a single task variable that is a pointer to a dynamically allocated structure containing the task's private "global" data.

A critical point with per-task variables is that each task must separately request that the same global variable is per-task private.

5.2.9 Building a Task Attribute Set

In general, an attribute set is built by a bitwise OR of the desired components. The set of valid task attribute components is listed below:

- `RTEMS_NO_FLOATING_POINT` - does not use coprocessor (default)
- `RTEMS_FLOATING_POINT` - uses numeric coprocessor
- `RTEMS_LOCAL` - local task (default)
- `RTEMS_GLOBAL` - global task

Attribute values are specifically designed to be mutually exclusive, therefore bitwise OR and addition operations are equivalent as long as each attribute appears exactly once in

the component list. A component listed as a default is not required to appear in the component list, although it is a good programming practice to specify default components. If all defaults are desired, then `RTEMS_DEFAULT_ATTRIBUTES` should be used.

This example demonstrates the `attribute_set` parameter needed to create a local task which utilizes the numeric coprocessor. The `attribute_set` parameter could be `RTEMS_FLOATING_POINT` or `RTEMS_LOCAL | RTEMS_FLOATING_POINT`. The `attribute_set` parameter can be set to `RTEMS_FLOATING_POINT` because `RTEMS_LOCAL` is the default for all created tasks. If the task were global and used the numeric coprocessor, then the `attribute_set` parameter would be `RTEMS_GLOBAL | RTEMS_FLOATING_POINT`.

5.2.10 Building a Mode and Mask

In general, a mode and its corresponding mask is built by a bitwise OR of the desired components. The set of valid mode constants and each mode's corresponding mask constant is listed below:

- `RTEMS_PREEMPT` is masked by `RTEMS_PREEMPT_MASK` and enables preemption
- `RTEMS_NO_PREEMPT` is masked by `RTEMS_PREEMPT_MASK` and disables preemption
- `RTEMS_NO_TIMESLICE` is masked by `RTEMS_TIMESLICE_MASK` and disables timeslicing
- `RTEMS_TIMESLICE` is masked by `RTEMS_TIMESLICE_MASK` and enables timeslicing
- `RTEMS_ASR` is masked by `RTEMS_ASR_MASK` and enables ASR processing
- `RTEMS_NO_ASR` is masked by `RTEMS_ASR_MASK` and disables ASR processing
- `RTEMS_INTERRUPT_LEVEL(0)` is masked by `RTEMS_INTERRUPT_MASK` and enables all interrupts
- `RTEMS_INTERRUPT_LEVEL(n)` is masked by `RTEMS_INTERRUPT_MASK` and sets interrupts level `n`

Mode values are specifically designed to be mutually exclusive, therefore bitwise OR and addition operations are equivalent as long as each mode appears exactly once in the component list. A mode component listed as a default is not required to appear in the mode component list, although it is a good programming practice to specify default components. If all defaults are desired, the mode `RTEMS_DEFAULT_MODES` and the mask `RTEMS_ALL_MODE_MASKS` should be used.

The following example demonstrates the mode and mask parameters used with the `rtems_task_mode` directive to place a task at interrupt level 3 and make it non-preemptible. The mode should be set to `RTEMS_INTERRUPT_LEVEL(3) | RTEMS_NO_PREEMPT` to indicate the desired preemption mode and interrupt level, while the mask parameter should be set to `RTEMS_INTERRUPT_MASK | RTEMS_NO_PREEMPT_MASK` to indicate that the calling task's interrupt level and preemption mode are being altered.

5.3 Operations

5.3.1 Creating Tasks

The `rtems_task_create` directive creates a task by allocating a task control block, assigning the task a user-specified name, allocating it a stack and floating point context area, setting

a user-specified initial priority, setting a user-specified initial mode, and assigning it a task ID. Newly created tasks are initially placed in the dormant state. All RTEMS tasks execute in the most privileged mode of the processor.

5.3.2 Obtaining Task IDs

When a task is created, RTEMS generates a unique task ID and assigns it to the created task until it is deleted. The task ID may be obtained by either of two methods. First, as the result of an invocation of the `rtems_task_create` directive, the task ID is stored in a user provided location. Second, the task ID may be obtained later using the `rtems_task_ident` directive. The task ID is used by other directives to manipulate this task.

5.3.3 Starting and Restarting Tasks

The `rtems_task_start` directive is used to place a dormant task in the ready state. This enables the task to compete, based on its current priority, for the processor and other system resources. Any actions, such as suspension or change of priority, performed on a task prior to starting it are nullified when the task is started.

With the `rtems_task_start` directive the user specifies the task's starting address and argument. The argument is used to communicate some startup information to the task. As part of this directive, RTEMS initializes the task's stack based upon the task's initial execution mode and start address. The starting argument is passed to the task in accordance with the target processor's calling convention.

The `rtems_task_restart` directive restarts a task at its initial starting address with its original priority and execution mode, but with a possibly different argument. The new argument may be used to distinguish between the original invocation of the task and subsequent invocations. The task's stack and control block are modified to reflect their original creation values. Although references to resources that have been requested are cleared, resources allocated by the task are NOT automatically returned to RTEMS. A task cannot be restarted unless it has previously been started (i.e. dormant tasks cannot be restarted). All restarted tasks are placed in the ready state.

5.3.4 Suspending and Resuming Tasks

The `rtems_task_suspend` directive is used to place either the caller or another task into a suspended state. The task remains suspended until a `rtems_task_resume` directive is issued. This implies that a task may be suspended as well as blocked waiting either to acquire a resource or for the expiration of a timer.

The `rtems_task_resume` directive is used to remove another task from the suspended state. If the task is not also blocked, resuming it will place it in the ready state, allowing it to once again compete for the processor and resources. If the task was blocked as well as suspended, this directive clears the suspension and leaves the task in the blocked state.

Suspending a task which is already suspended or resuming a task which is not suspended is considered an error. The `rtems_task_is_suspended` can be used to determine if a task is currently suspended.

5.3.5 Delaying the Currently Executing Task

The `rtems_task_wake_after` directive creates a sleep timer which allows a task to go to sleep for a specified interval. The task is blocked until the delay interval has elapsed, at which time the task is unblocked. A task calling the `rtems_task_wake_after` directive with a delay interval of `RTEMS_YIELD_PROCESSOR` ticks will yield the processor to any other ready task of equal or greater priority and remain ready to execute.

The `rtems_task_wake_when` directive creates a sleep timer which allows a task to go to sleep until a specified date and time. The calling task is blocked until the specified date and time has occurred, at which time the task is unblocked.

5.3.6 Changing Task Priority

The `rtems_task_set_priority` directive is used to obtain or change the current priority of either the calling task or another task. If the new priority requested is `RTEMS_CURRENT_PRIORITY` or the task's actual priority, then the current priority will be returned and the task's priority will remain unchanged. If the task's priority is altered, then the task will be scheduled according to its new priority.

The `rtems_task_restart` directive resets the priority of a task to its original value.

5.3.7 Changing Task Mode

The `rtems_task_mode` directive is used to obtain or change the current execution mode of the calling task. A task's execution mode is used to enable preemption, timeslicing, ASR processing, and to set the task's interrupt level.

The `rtems_task_restart` directive resets the mode of a task to its original value.

5.3.8 Notepad Locations

RTEMS provides sixteen notepad locations for each task. Each notepad location may contain a note consisting of four bytes of information. RTEMS provides two directives, `rtems_task_set_note` and `rtems_task_get_note`, that enable a user to access and change the notepad locations. The `rtems_task_set_note` directive enables the user to set a task's notepad entry to a specified note. The `rtems_task_get_note` directive allows the user to obtain the note contained in any one of the sixteen notepads of a specified task.

5.3.9 Task Deletion

RTEMS provides the `rtems_task_delete` directive to allow a task to delete itself or any other task. This directive removes all RTEMS references to the task, frees the task's control block, removes it from resource wait queues, and deallocates its stack as well as the optional floating point context. The task's name and ID become inactive at this time, and any subsequent references to either of them is invalid. In fact, RTEMS may reuse the task ID for another task which is created later in the application.

Unexpired delay timers (i.e. those used by `rtems_task_wake_after` and `rtems_task_wake_when`) and timeout timers associated with the task are automatically deleted, however, other resources dynamically allocated by the task are NOT automatically returned to RTEMS. Therefore, before a task is deleted, all of its dynamically allocated resources should be deallocated by the user. This may be accomplished by instructing the task to

delete itself rather than directly deleting the task. Other tasks may instruct a task to delete itself by sending a "delete self" message, event, or signal, or by restarting the task with special arguments which instruct the task to delete itself.

5.4 Directives

This section details the task manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

5.4.1 TASK_CREATE - Create a task

CALLING SEQUENCE:

```

rtems_status_code rtems_task_create(
    rtems_name      name,
    rtems_task_priority initial_priority,
    size_t          stack_size,
    rtems_mode      initial_modes,
    rtems_attribute  attribute_set,
    rtems_id        *id
);

```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - task created successfully
 RTEMS_INVALID_ADDRESS - id is NULL
 RTEMS_INVALID_NAME - invalid task name
 RTEMS_INVALID_PRIORITY - invalid task priority
 RTEMS_MP_NOT_CONFIGURED - multiprocessing not configured
 RTEMS_TOO_MANY - too many tasks created
 RTEMS_UNSATISFIED - not enough memory for stack/FP context
 RTEMS_TOO_MANY - too many global objects

DESCRIPTION:

This directive creates a task which resides on the local node. It allocates and initializes a TCB, a stack, and an optional floating point context area. The mode parameter contains values which sets the task's initial execution mode. The `RTEMS_FLOATING_POINT` attribute should be specified if the created task is to use a numeric coprocessor. For performance reasons, it is recommended that tasks not using the numeric coprocessor should specify the `RTEMS_NO_FLOATING_POINT` attribute. If the `RTEMS_GLOBAL` attribute is specified, the task can be accessed from remote nodes. The task id, returned in `id`, is used in other task related directives to access the task. When created, a task is placed in the dormant state and can only be made ready to execute using the directive `rtems_task_start`.

NOTES:

This directive will not cause the calling task to be preempted.

Valid task priorities range from a high of 1 to a low of 255.

If the requested stack size is less than the configured minimum stack size, then RTEMS will use the configured minimum as the stack size for this task. In addition to being able to specify the task stack size as a integer, there are two constants which may be specified:

- RTEMS_MINIMUM_STACK_SIZE** is the minimum stack size **RECOMMENDED** for use on this processor. This value is selected by the RTEMS developers conservatively to minimize the risk of blown stacks for most user applications. Using this constant when specifying the task stack size, indicates that the stack size will be at least `RTEMS_MINIMUM_STACK_SIZE` bytes in size. If the user configured minimum stack size is larger than the recommended minimum, then it will be used.

- `RTEMS_CONFIGURED_MINIMUM_STACK_SIZE` indicates that this task is to be created with a stack size of the minimum stack size that was configured by the application. If not explicitly configured by the application, the default configured minimum stack size is the processor dependent value `RTEMS_MINIMUM_STACK_SIZE`. Since this uses the configured minimum stack size value, you may get a stack size that is smaller or larger than the recommended minimum. This can be used to provide large stacks for all tasks on complex applications or small stacks on applications that are trying to conserve memory.

Application developers should consider the stack usage of the device drivers when calculating the stack size required for tasks which utilize the driver.

The following task attribute constants are defined by RTEMS:

- `RTEMS_NO_FLOATING_POINT` - does not use coprocessor (default)
- `RTEMS_FLOATING_POINT` - uses numeric coprocessor
- `RTEMS_LOCAL` - local task (default)
- `RTEMS_GLOBAL` - global task

The following task mode constants are defined by RTEMS:

- `RTEMS_PREEMPT` - enable preemption (default)
- `RTEMS_NO_PREEMPT` - disable preemption
- `RTEMS_NO_TIMESLICE` - disable timeslicing (default)
- `RTEMS_TIMESLICE` - enable timeslicing
- `RTEMS_ASR` - enable ASR processing (default)
- `RTEMS_NO_ASR` - disable ASR processing
- `RTEMS_INTERRUPT_LEVEL(0)` - enable all interrupts (default)
- `RTEMS_INTERRUPT_LEVEL(n)` - execute at interrupt level n

The interrupt level portion of the task execution mode supports a maximum of 256 interrupt levels. These levels are mapped onto the interrupt levels actually supported by the target processor in a processor dependent fashion.

Tasks should not be made global unless remote tasks must interact with them. This avoids the system overhead incurred by the creation of a global task. When a global task is created, the task's name and id must be transmitted to every node in the system for insertion in the local copy of the global object table.

The total number of global objects, including tasks, is limited by the `maximum_global_objects` field in the Configuration Table.

5.4.2 TASK_IDENT - Get ID of a task

CALLING SEQUENCE:

```
rtcms_status_code rtcms_task_ident(  
    rtcms_name  name,  
    uint32_t    node,  
    rtcms_id    *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - task identified successfully

RTEMS_INVALID_ADDRESS - id is NULL

RTEMS_INVALID_NAME - invalid task name

RTEMS_INVALID_NODE - invalid node id

DESCRIPTION:

This directive obtains the task id associated with the task name specified in name. A task may obtain its own id by specifying RTEMS_SELF or its own task name in name. If the task name is not unique, then the task id returned will match one of the tasks with that name. However, this task id is not guaranteed to correspond to the desired task. The task id, returned in id, is used in other task related directives to access the task.

NOTES:

This directive will not cause the running task to be preempted.

If node is RTEMS_SEARCH_ALL_NODES, all nodes are searched with the local node being searched first. All other nodes are searched with the lowest numbered node searched first.

If node is a valid node number which does not represent the local node, then only the tasks exported by the designated node are searched.

This directive does not generate activity on remote nodes. It accesses only the local copy of the global object table.

5.4.3 TASK_SELF - Obtain ID of caller

CALLING SEQUENCE:

```
rtems_id rtems_task_self(void);
```

DIRECTIVE STATUS CODES:

Returns the object Id of the calling task.

DESCRIPTION:

This directive returns the Id of the calling task.

NOTES:

If called from an interrupt service routine, this directive will return the Id of the interrupted task.

5.4.4 TASK_START - Start a task

CALLING SEQUENCE:

```
rtems_status_code rtems_task_start(  
    rtems_id          id,  
    rtems_task_entry  entry_point,  
    rtems_task_argument argument  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - task started successfully
RTEMS_INVALID_ADDRESS - invalid task entry point
RTEMS_INVALID_ID - invalid task id
RTEMS_INCORRECT_STATE - task not in the dormant state
RTEMS_ILLEGAL_ON_REMOTE_OBJECT - cannot start remote task

DESCRIPTION:

This directive readies the task, specified by `id`, for execution based on the priority and execution mode specified when the task was created. The starting address of the task is given in `entry_point`. The task's starting argument is contained in `argument`. This argument can be a single value or used as an index into an array of parameter blocks. The type of this numeric argument is an unsigned integer type with the property that any valid pointer to void can be converted to this type and then converted back to a pointer to void. The result will compare equal to the original pointer.

NOTES:

The calling task will be preempted if its preemption mode is enabled and the task being started has a higher priority.

Any actions performed on a dormant task such as suspension or change of priority are nullified when the task is initiated via the `rtems_task_start` directive.

5.4.5 TASK_RESTART - Restart a task

CALLING SEQUENCE:

```
rtems_status_code rtems_task_restart(  
    rtems_id          id,  
    rtems_task_argument argument  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - task restarted successfully

RTEMS_INVALID_ID - task id invalid

RTEMS_INCORRECT_STATE - task never started

RTEMS_ILLEGAL_ON_REMOTE_OBJECT - cannot restart remote task

DESCRIPTION:

This directive resets the task specified by `id` to begin execution at its original starting address. The task's priority and execution mode are set to the original creation values. If the task is currently blocked, RTEMS automatically makes the task ready. A task can be restarted from any state, except the dormant state.

The task's starting argument is contained in `argument`. This argument can be a single value or an index into an array of parameter blocks. The type of this numeric argument is an unsigned integer type with the property that any valid pointer to void can be converted to this type and then converted back to a pointer to void. The result will compare equal to the original pointer. This new argument may be used to distinguish between the initial `rtems_task_start` of the task and any ensuing calls to `rtems_task_restart` of the task. This can be beneficial in deleting a task. Instead of deleting a task using the `rtems_task_delete` directive, a task can delete another task by restarting that task, and allowing that task to release resources back to RTEMS and then delete itself.

NOTES:

If `id` is `RTEMS_SELF`, the calling task will be restarted and will not return from this directive.

The calling task will be preempted if its preemption mode is enabled and the task being restarted has a higher priority.

The task must reside on the local node, even if the task was created with the `RTEMS_GLOBAL` option.

5.4.6 TASK_DELETE - Delete a task

CALLING SEQUENCE:

```
rtcms_status_code rtcms_task_delete(  
    rtcms_id id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - task restarted successfully

RTEMS_INVALID_ID - task id invalid

RTEMS_ILLEGAL_ON_REMOTE_OBJECT - cannot restart remote task

DESCRIPTION:

This directive deletes a task, either the calling task or another task, as specified by id. RTEMS stops the execution of the task and reclaims the stack memory, any allocated delay or timeout timers, the TCB, and, if the task is `RTEMS_FLOATING_POINT`, its floating point context area. RTEMS does not reclaim the following resources: region segments, partition buffers, semaphores, timers, or rate monotonic periods.

NOTES:

A task is responsible for releasing its resources back to RTEMS before deletion. To insure proper deallocation of resources, a task should not be deleted unless it is unable to execute or does not hold any RTEMS resources. If a task holds RTEMS resources, the task should be allowed to deallocate its resources before deletion. A task can be directed to release its resources and delete itself by restarting it with a special argument or by sending it a message, an event, or a signal.

Deletion of the current task (`RTEMS_SELF`) will force RTEMS to select another task to execute.

When a global task is deleted, the task id must be transmitted to every node in the system for deletion from the local copy of the global object table.

The task must reside on the local node, even if the task was created with the `RTEMS_GLOBAL` option.

5.4.7 TASK_SUSPEND - Suspend a task

CALLING SEQUENCE:

```
rtems_status_code rtems_task_suspend(  
    rtems_id id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - task restarted successfully

RTEMS_INVALID_ID - task id invalid

RTEMS_ALREADY_SUSPENDED - task already suspended

DESCRIPTION:

This directive suspends the task specified by id from further execution by placing it in the suspended state. This state is additive to any other blocked state that the task may already be in. The task will not execute again until another task issues the `rtems_task_resume` directive for this task and any blocked state has been removed.

NOTES:

The requesting task can suspend itself by specifying `RTEMS_SELF` as id. In this case, the task will be suspended and a successful return code will be returned when the task is resumed.

Suspending a global task which does not reside on the local node will generate a request to the remote node to suspend the specified task.

If the task specified by id is already suspended, then the `RTEMS_ALREADY_SUSPENDED` status code is returned.

5.4.8 TASK_RESUME - Resume a task

CALLING SEQUENCE:

```
rtems_status_code rtems_task_resume(  
    rtems_id id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - task restarted successfully

RTEMS_INVALID_ID - task id invalid

RTEMS_INCORRECT_STATE - task not suspended

DESCRIPTION:

This directive removes the task specified by id from the suspended state. If the task is in the ready state after the suspension is removed, then it will be scheduled to run. If the task is still in a blocked state after the suspension is removed, then it will remain in that blocked state.

NOTES:

The running task may be preempted if its preemption mode is enabled and the local task being resumed has a higher priority.

Resuming a global task which does not reside on the local node will generate a request to the remote node to resume the specified task.

If the task specified by id is not suspended, then the RTEMS_INCORRECT_STATE status code is returned.

5.4.9 TASK_IS_SUSPENDED - Determine if a task is Suspended

CALLING SEQUENCE:

```
rtems_status_code rtems_task_is_suspended(  
    rtems_id id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - task is NOT suspended

RTEMS_ALREADY_SUSPENDED - task is currently suspended

RTEMS_INVALID_ID - task id invalid

RTEMS_ILLEGAL_ON_REMOTE_OBJECT - not supported on remote tasks

DESCRIPTION:

This directive returns a status code indicating whether or not the specified task is currently suspended.

NOTES:

This operation is not currently supported on remote tasks.

5.4.10 TASK_SET_PRIORITY - Set task priority

CALLING SEQUENCE:

```
rtcms_status_code rtcms_task_set_priority(  
    rtcms_id      id,  
    rtcms_task_priority new_priority,  
    rtcms_task_priority *old_priority  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - task priority set successfully

RTEMS_INVALID_ID - invalid task id

RTEMS_INVALID_ADDRESS - invalid return argument pointer

RTEMS_INVALID_PRIORITY - invalid task priority

DESCRIPTION:

This directive manipulates the priority of the task specified by id. An id of RTEMS_SELF is used to indicate the calling task. When new_priority is not equal to RTEMS_CURRENT_PRIORITY, the specified task's previous priority is returned in old_priority. When new_priority is RTEMS_CURRENT_PRIORITY, the specified task's current priority is returned in old_priority. Valid priorities range from a high of 1 to a low of 255.

NOTES:

The calling task may be preempted if its preemption mode is enabled and it lowers its own priority or raises another task's priority.

Setting the priority of a global task which does not reside on the local node will generate a request to the remote node to change the priority of the specified task.

If the task specified by id is currently holding any binary semaphores which use the priority inheritance algorithm, then the task's priority cannot be lowered immediately. If the task's priority were lowered immediately, then priority inversion results. The requested lowering of the task's priority will occur when the task has released all priority inheritance binary semaphores. The task's priority can be increased regardless of the task's use of priority inheritance binary semaphores.

5.4.11 TASK_MODE - Change the current task mode

CALLING SEQUENCE:

```

rtems_status_code rtems_task_mode(
    rtems_mode  mode_set,
    rtems_mode  mask,
    rtems_mode *previous_mode_set
);

```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - task mode set successfully

RTEMS_INVALID_ADDRESS - `previous_mode_set` is NULL

DESCRIPTION:

This directive manipulates the execution mode of the calling task. A task's execution mode enables and disables preemption, timeslicing, asynchronous signal processing, as well as specifying the current interrupt level. To modify an execution mode, the mode class(es) to be changed must be specified in the mask parameter and the desired mode(s) must be specified in the mode parameter.

NOTES:

The calling task will be preempted if it enables preemption and a higher priority task is ready to run.

Enabling timeslicing has no effect if preemption is disabled. For a task to be timesliced, that task must have both preemption and timeslicing enabled.

A task can obtain its current execution mode, without modifying it, by calling this directive with a mask value of `RTEMS_CURRENT_MODE`.

To temporarily disable the processing of a valid ASR, a task should call this directive with the `RTEMS_NO_ASR` indicator specified in mode.

The set of task mode constants and each mode's corresponding mask constant is provided in the following table:

- `RTEMS_PREEMPT` is masked by `RTEMS_PREEMPT_MASK` and enables preemption
- `RTEMS_NO_PREEMPT` is masked by `RTEMS_PREEMPT_MASK` and disables preemption
- `RTEMS_NO_TIMESLICE` is masked by `RTEMS_TIMESLICE_MASK` and disables timeslicing
- `RTEMS_TIMESLICE` is masked by `RTEMS_TIMESLICE_MASK` and enables timeslicing
- `RTEMS_ASR` is masked by `RTEMS_ASR_MASK` and enables ASR processing
- `RTEMS_NO_ASR` is masked by `RTEMS_ASR_MASK` and disables ASR processing
- `RTEMS_INTERRUPT_LEVEL(0)` is masked by `RTEMS_INTERRUPT_MASK` and enables all interrupts
- `RTEMS_INTERRUPT_LEVEL(n)` is masked by `RTEMS_INTERRUPT_MASK` and sets interrupt level `n`

5.4.12 TASK_GET_NOTE - Get task notepad entry

CALLING SEQUENCE:

```
rtems_status_code rtems_task_get_note(  
    rtems_id id,  
    uint32_t notepad,  
    uint32_t *note  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - note obtained successfully

RTEMS_INVALID_ADDRESS - `note` is NULL

RTEMS_INVALID_ID - invalid task id

RTEMS_INVALID_NUMBER - invalid notepad location

DESCRIPTION:

This directive returns the note contained in the notepad location of the task specified by `id`.

NOTES:

This directive will not cause the running task to be preempted.

If `id` is set to `RTEMS_SELF`, the calling task accesses its own notepad.

The sixteen notepad locations can be accessed using the constants `RTEMS_NOTEPAD_0` through `RTEMS_NOTEPAD_15`.

Getting a note of a global task which does not reside on the local node will generate a request to the remote node to obtain the notepad entry of the specified task.

5.4.13 TASK_SET_NOTE - Set task notepad entry

CALLING SEQUENCE:

```
rtems_status_code rtems_task_set_note(  
    rtems_id id,  
    uint32_t notepad,  
    uint32_t note  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - task's note set successfully

RTEMS_INVALID_ID - invalid task id

RTEMS_INVALID_NUMBER - invalid notepad location

DESCRIPTION:

This directive sets the notepad entry for the task specified by id to the value note.

NOTES:

If id is set to RTEMS_SELF, the calling task accesses its own notepad locations.

This directive will not cause the running task to be preempted.

The sixteen notepad locations can be accessed using the constants RTEMS_NOTEPAD_0 through RTEMS_NOTEPAD_15.

Setting a notepad location of a global task which does not reside on the local node will generate a request to the remote node to set the specified notepad entry.

5.4.14 TASK_WAKE_AFTER - Wake up after interval

CALLING SEQUENCE:

```
    rtems_status_code rtems_task_wake_after(  
        rtems_interval ticks  
    );
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - always successful

DESCRIPTION:

This directive blocks the calling task for the specified number of system clock ticks. When the requested interval has elapsed, the task is made ready. The `rtems_clock_tick` directive automatically updates the delay period.

NOTES:

Setting the system date and time with the `rtems_clock_set` directive has no effect on a `rtems_task_wake_after` blocked task.

A task may give up the processor and remain in the ready state by specifying a value of `RTEMS_YIELD_PROCESSOR` in ticks.

The maximum timer interval that can be specified is the maximum value which can be represented by the `uint32_t` type.

A clock tick is required to support the functionality of this directive.

5.4.15 TASK_WAKE_WHEN - Wake up when specified

CALLING SEQUENCE:

```
rtems_status_code rtems_task_wake_when(  
    rtems_time_of_day *time_buffer  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - awakened at date/time successfully

RTEMS_INVALID_ADDRESS - `time_buffer` is NULL

RTEMS_INVALID_TIME_OF_DAY - invalid time buffer

RTEMS_NOT_DEFINED - system date and time is not set

DESCRIPTION:

This directive blocks a task until the date and time specified in `time_buffer`. At the requested date and time, the calling task will be unblocked and made ready to execute.

NOTES:

The ticks portion of `time_buffer` structure is ignored. The timing granularity of this directive is a second.

A clock tick is required to support the functionality of this directive.

5.4.16 ITERATE_OVER_ALL_THREADS - Iterate Over Tasks

CALLING SEQUENCE:

```
typedef void (*rtems_per_thread_routine)(
    Thread_Control *the_thread
);

void rtems_iterate_over_all_threads(
    rtems_per_thread_routine routine
);
```

DIRECTIVE STATUS CODES: NONE

DESCRIPTION:

This directive iterates over all of the existant threads in the system and invokes **routine** on each of them. The user should be careful in accessing the contents of **the_thread**.

This routine is intended for use in diagnostic utilities and is not intended for routine use in an operational system.

NOTES:

There is NO protection while this routine is called. Thus it is possible that **the_thread** could be deleted while this is operating. By not having protection, the user is free to invoke support routines from the C Library which require semaphores for data structures.

5.4.17 TASK_VARIABLE_ADD - Associate per task variable

CALLING SEQUENCE:

```
rtems_status_code rtems_task_variable_add(
    rtems_id  tid,
    void      **task_variable,
    void      (*dtor)(void *)
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - per task variable added successfully

RTEMS_INVALID_ADDRESS - `task_variable` is NULL

RTEMS_INVALID_ID - invalid task id

RTEMS_NO_MEMORY - invalid task id

RTEMS_ILLEGAL_ON_REMOTE_OBJECT - not supported on remote tasks

DESCRIPTION:

This directive adds the memory location specified by the `ptr` argument to the context of the given task. The variable will then be private to the task. The task can access and modify the variable, but the modifications will not appear to other tasks, and other tasks' modifications to that variable will not affect the value seen by the task. This is accomplished by saving and restoring the variable's value each time a task switch occurs to or from the calling task. If the `dtor` argument is non-NULL it specifies the address of a 'destructor' function which will be called when the task is deleted. The argument passed to the destructor function is the task's value of the variable.

NOTES:

Task variables increase the context switch time to and from the tasks that own them so it is desirable to minimize the number of task variables. One efficient method is to have a single task variable that is a pointer to a dynamically allocated structure containing the task's private 'global' data. In this case the destructor function could be 'free'.

5.4.18 TASK_VARIABLE_GET - Obtain value of a per task variable

CALLING SEQUENCE:

```
rtems_status_code rtems_task_variable_get(
    rtems_id tid,
    void **task_variable,
    void **task_variable_value
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - per task variable added successfully
RTEMS_INVALID_ADDRESS - `task_variable` is NULL
RTEMS_INVALID_ADDRESS - `task_variable_value` is NULL
RTEMS_INVALID_ADDRESS - `task_variable` is not found
RTEMS_NO_MEMORY - invalid task id
RTEMS_ILLEGAL_ON_REMOTE_OBJECT - not supported on remote tasks

DESCRIPTION:

This directive looks up the private value of a task variable for a specified task and stores that value in the location pointed to by the result argument. The specified task is usually not the calling task, which can get its private value by directly accessing the variable.

NOTES:

If you change memory which `task_variable_value` points to, remember to declare that memory as volatile, so that the compiler will optimize it correctly. In this case both the pointer `task_variable_value` and data referenced by `task_variable_value` should be considered volatile.

5.4.19 TASK_VARIABLE_DELETE - Remove per task variable

CALLING SEQUENCE:

```
rtcms_status_code rtcms_task_variable_delete(  
    rtcms_id id,  
    void **task_variable  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - per task variable added successfully

RTEMS_INVALID_ID - invalid task id

RTEMS_NO_MEMORY - invalid task id

RTEMS_INVALID_ADDRESS - `task_variable` is NULL

RTEMS_ILLEGAL_ON_REMOTE_OBJECT - not supported on remote tasks

DESCRIPTION:

This directive removes the given location from a task's context.

NOTES:

NONE

6 Interrupt Manager

6.1 Introduction

Any real-time executive must provide a mechanism for quick response to externally generated interrupts to satisfy the critical time constraints of the application. The interrupt manager provides this mechanism for RTEMS. This manager permits quick interrupt response times by providing the critical ability to alter task execution which allows a task to be preempted upon exit from an ISR. The interrupt manager includes the following directive:

- `rtems_interrupt_catch` - Establish an ISR
- `rtems_interrupt_disable` - Disable Interrupts
- `rtems_interrupt_enable` - Enable Interrupts
- `rtems_interrupt_flash` - Flash Interrupt
- `rtems_interrupt_is_in_progress` - Is an ISR in Progress

6.2 Background

6.2.1 Processing an Interrupt

The interrupt manager allows the application to connect a function to a hardware interrupt vector. When an interrupt occurs, the processor will automatically vector to RTEMS. RTEMS saves and restores all registers which are not preserved by the normal C calling convention for the target processor and invokes the user's ISR. The user's ISR is responsible for processing the interrupt, clearing the interrupt if necessary, and device specific manipulation.

The `rtems_interrupt_catch` directive connects a procedure to an interrupt vector. The vector number is managed using the `rtems_vector_number` data type.

The interrupt service routine is assumed to abide by these conventions and have a prototype similar to the following:

```
rtems_isr user_isr(  
    rtems_vector_number vector  
);
```

The vector number argument is provided by RTEMS to allow the application to identify the interrupt source. This could be used to allow a single routine to service interrupts from multiple instances of the same device. For example, a single routine could service interrupts from multiple serial ports and use the vector number to identify which port requires servicing.

To minimize the masking of lower or equal priority level interrupts, the ISR should perform the minimum actions required to service the interrupt. Other non-essential actions should be handled by application tasks. Once the user's ISR has completed, it returns control to the RTEMS interrupt manager which will perform task dispatching and restore the registers saved before the ISR was invoked.

The RTEMS interrupt manager guarantees that proper task scheduling and dispatching are performed at the conclusion of an ISR. A system call made by the ISR may have readied a task of higher priority than the interrupted task. Therefore, when the ISR completes, the postponed dispatch processing must be performed. No dispatch processing is performed as part of directives which have been invoked by an ISR.

Applications must adhere to the following rule if proper task scheduling and dispatching is to be performed:

The interrupt manager must be used for all ISRs which may be interrupted by the highest priority ISR which invokes an RTEMS directive.

Consider a processor which allows a numerically low interrupt level to interrupt a numerically greater interrupt level. In this example, if an RTEMS directive is used in a level 4 ISR, then all ISRs which execute at levels 0 through 4 must use the interrupt manager.

Interrupts are nested whenever an interrupt occurs during the execution of another ISR. RTEMS supports efficient interrupt nesting by allowing the nested ISRs to terminate without performing any dispatch processing. Only when the outermost ISR terminates will the postponed dispatching occur.

6.2.2 RTEMS Interrupt Levels

Many processors support multiple interrupt levels or priorities. The exact number of interrupt levels is processor dependent. RTEMS internally supports 256 interrupt levels which are mapped to the processor's interrupt levels. For specific information on the mapping between RTEMS and the target processor's interrupt levels, refer to the Interrupt Processing chapter of the Applications Supplement document for a specific target processor.

6.2.3 Disabling of Interrupts by RTEMS

During the execution of directive calls, critical sections of code may be executed. When these sections are encountered, RTEMS disables all maskable interrupts before the execution of the section and restores them to the previous level upon completion of the section. RTEMS has been optimized to ensure that interrupts are disabled for a minimum length of time. The maximum length of time interrupts are disabled by RTEMS is processor dependent and is detailed in the Timing Specification chapter of the Applications Supplement document for a specific target processor.

Non-maskable interrupts (NMI) cannot be disabled, and ISRs which execute at this level MUST NEVER issue RTEMS system calls. If a directive is invoked, unpredictable results may occur due to the inability of RTEMS to protect its critical sections. However, ISRs that make no system calls may safely execute as non-maskable interrupts.

6.3 Operations

6.3.1 Establishing an ISR

The `rtems_interrupt_catch` directive establishes an ISR for the system. The address of the ISR and its associated CPU vector number are specified to this directive. This directive installs the RTEMS interrupt wrapper in the processor's Interrupt Vector Table and the

address of the user's ISR in the RTEMS' Vector Table. This directive returns the previous contents of the specified vector in the RTEMS' Vector Table.

6.3.2 Directives Allowed from an ISR

Using the interrupt manager ensures that RTEMS knows when a directive is being called from an ISR. The ISR may then use system calls to synchronize itself with an application task. The synchronization may involve messages, events or signals being passed by the ISR to the desired task. Directives invoked by an ISR must operate only on objects which reside on the local node. The following is a list of RTEMS system calls that may be made from an ISR:

- Task Management

Although it is acceptable to operate on the RTEMS_SELF task (e.g. the currently executing task), while in an ISR, this will refer to the interrupted task. Most of the time, it is an application implementation error to use RTEMS_SELF from an ISR.

- `rtems_task_get_note`
- `rtems_task_set_note`
- `rtems_task_suspend`
- `rtems_task_resume`

- Interrupt Management

- `rtems_interrupt_enable`
- `rtems_interrupt_disable`
- `rtems_interrupt_flash`
- `rtems_interrupt_is_in_progress`
- `rtems_interrupt_catch`

- Clock Management

- `rtems_clock_set`
- `rtems_clock_get`
- `rtems_clock_get_tod`
- `rtems_clock_get_tod_timeval`
- `rtems_clock_get_seconds_since_epoch`
- `rtems_clock_get_ticks_per_second`
- `rtems_clock_get_ticks_since_boot`
- `rtems_clock_get_uptime`
- `rtems_clock_set_nanoseconds_extension`
- `rtems_clock_tick`

- Message, Event, and Signal Management

- `rtems_message_queue_send`
- `rtems_message_queue_urgent`
- `rtems_event_send`
- `rtems_signal_send`

- Semaphore Management
 - `rtems_semaphore_release`
- Dual-Ported Memory Management
 - `rtems_port_external_to_internal`
 - `rtems_port_internal_to_external`
- IO Management

The following services are safe to call from an ISR if and only if the device driver service invoked is also safe. The IO Manager itself is safe but the invoked driver entry point may or may not be.

- `rtems_io_initialize`
 - `rtems_io_open`
 - `rtems_io_close`
 - `rtems_io_read`
 - `rtems_io_write`
 - `rtems_io_control`
- Fatal Error Management
 - `rtems_fatal_error_occurred`
- Multiprocessing
 - `rtems_multiprocessing_announce`

6.4 Directives

This section details the interrupt manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

6.4.1 INTERRUPT_CATCH - Establish an ISR

CALLING SEQUENCE:

```
rtems_status_code rtems_interrupt_catch(  
    rtems_isr_entry    new_isr_handler,  
    rtems_vector_number vector,  
    rtems_isr_entry    *old_isr_handler  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - ISR established successfully

RTEMS_INVALID_NUMBER - illegal vector number

RTEMS_INVALID_ADDRESS - illegal ISR entry point or invalid old_isr_handler

DESCRIPTION:

This directive establishes an interrupt service routine (ISR) for the specified interrupt vector number. The `new_isr_handler` parameter specifies the entry point of the ISR. The entry point of the previous ISR for the specified vector is returned in `old_isr_handler`.

To release an interrupt vector, pass the old handler's address obtained when the vector was first capture.

NOTES:

This directive will not cause the calling task to be preempted.

6.4.2 INTERRUPT_DISABLE - Disable Interrupts

CALLING SEQUENCE:

```
void rtems_interrupt_disable(  
    rtems_interrupt_level level  
);
```

```
/* this is implemented as a macro and sets level as a side-effect */
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive disables all maskable interrupts and returns the previous `level`. A later invocation of the `rtems_interrupt_enable` directive should be used to restore the interrupt level.

NOTES:

This directive will not cause the calling task to be preempted.

This directive is implemented as a macro which modifies the `level` parameter.

6.4.3 INTERRUPT_ENABLE - Enable Interrupts

CALLING SEQUENCE:

```
void rtems_interrupt_enable(  
    rtems_interrupt_level level  
);
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive enables maskable interrupts to the `level` which was returned by a previous call to `rtems_interrupt_disable`. Immediately prior to invoking this directive, maskable interrupts should be disabled by a call to `rtems_interrupt_disable` and will be enabled when this directive returns to the caller.

NOTES:

This directive will not cause the calling task to be preempted.

6.4.4 INTERRUPT_FLASH - Flash Interrupts

CALLING SEQUENCE:

```
void rtems_interrupt_flash(  
    rtems_interrupt_level level  
);
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive temporarily enables maskable interrupts to the `level` which was returned by a previous call to `rtems_interrupt_disable`. Immediately prior to invoking this directive, maskable interrupts should be disabled by a call to `rtems_interrupt_disable` and will be redissabled when this directive returns to the caller.

NOTES:

This directive will not cause the calling task to be preempted.

6.4.5 INTERRUPT_IS_IN_PROGRESS - Is an ISR in Progress

CALLING SEQUENCE:

```
bool rtems_interrupt_is_in_progress( void );
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive returns **TRUE** if the processor is currently servicing an interrupt and **FALSE** otherwise. A return value of **TRUE** indicates that the caller is an interrupt service routine, **NOT** a task. The directives available to an interrupt service routine are restricted.

NOTES:

This directive will not cause the calling task to be preempted.

7 Clock Manager

7.1 Introduction

The clock manager provides support for time of day and other time related capabilities. The directives provided by the clock manager are:

- `rtems_clock_set` - Set date and time
- `rtems_clock_get` - Get date and time information
- `rtems_clock_get_tod` - Get date and time in TOD format
- `rtems_clock_get_tod_timeval` - Get date and time in timeval format
- `rtems_clock_get_seconds_since_epoch` - Get seconds since epoch
- `rtems_clock_get_ticks_per_second` - Get ticks per second
- `rtems_clock_get_ticks_since_boot` - Get ticks since boot
- `rtems_clock_get_uptime` - Get time since boot
- `rtems_clock_set_nanoseconds_extension` - Install the nanoseconds since last tick handler
- `rtems_clock_tick` - Announce a clock tick

7.2 Background

7.2.1 Required Support

For the features provided by the clock manager to be utilized, periodic timer interrupts are required. Therefore, a real-time clock or hardware timer is necessary to create the timer interrupts. The `rtems_clock_tick` directive is normally called by the timer ISR to announce to RTEMS that a system clock tick has occurred. Elapsed time is measured in ticks. A tick is defined to be an integral number of microseconds which is specified by the user in the Configuration Table.

7.2.2 Time and Date Data Structures

The clock facilities of the clock manager operate upon calendar time. These directives utilize the following date and time structure for the native time and date format:

```
struct rtems_tod_control {
    uint32_t year;    /* greater than 1987 */
    uint32_t month;   /* 1 - 12 */
    uint32_t day;     /* 1 - 31 */
    uint32_t hour;    /* 0 - 23 */
    uint32_t minute;  /* 0 - 59 */
    uint32_t second;  /* 0 - 59 */
    uint32_t ticks;   /* elapsed between seconds */
};

typedef struct rtems_tod_control rtems_time_of_day;
```

The native date and time format is the only format supported when setting the system date and time using the `rtems_clock_set` directive. Some applications expect to operate on a "UNIX-style" date and time data structure. The `rtems_clock_get_tod_timeval` always returns the date and time in `struct timeval` format. The `rtems_clock_get` directive can optionally return the current date and time in this format.

The `struct timeval` data structure has two fields: `tv_sec` and `tv_usec` which are seconds and microseconds, respectively. The `tv_sec` field in this data structure is the number of seconds since the POSIX epoch of January 1, 1970 but will never be prior to the RTEMS epoch of January 1, 1988.

7.2.3 Clock Tick and Timeslicing

Timeslicing is a task scheduling discipline in which tasks of equal priority are executed for a specific period of time before control of the CPU is passed to another task. It is also sometimes referred to as the automatic round-robin scheduling algorithm. The length of time allocated to each task is known as the quantum or timeslice.

The system's timeslice is defined as an integral number of ticks, and is specified in the Configuration Table. The timeslice is defined for the entire system of tasks, but timeslicing is enabled and disabled on a per task basis.

The `rtems_clock_tick` directive implements timeslicing by decrementing the running task's time-remaining counter when both timeslicing and preemption are enabled. If the task's timeslice has expired, then that task will be preempted if there exists a ready task of equal priority.

7.2.4 Delays

A sleep timer allows a task to delay for a given interval or up until a given time, and then wake and continue execution. This type of timer is created automatically by the `rtems_task_wake_after` and `rtems_task_wake_when` directives and, as a result, does not have an RTEMS ID. Once activated, a sleep timer cannot be explicitly deleted. Each task may activate one and only one sleep timer at a time.

7.2.5 Timeouts

Timeouts are a special type of timer automatically created when the timeout option is used on the `rtems_message_queue_receive`, `rtems_event_receive`, `rtems_semaphore_obtain` and `rtems_region_get_segment` directives. Each task may have one and only one timeout active at a time. When a timeout expires, it unblocks the task with a timeout status code.

7.3 Operations

7.3.1 Announcing a Tick

RTEMS provides the `rtems_clock_tick` directive which is called from the user's real-time clock ISR to inform RTEMS that a tick has elapsed. The tick frequency value, defined in microseconds, is a configuration parameter found in the Configuration Table. RTEMS divides one million microseconds (one second) by the number of microseconds per tick to determine the number of calls to the `rtems_clock_tick` directive per second. The frequency

of `rtems_clock_tick` calls determines the resolution (granularity) for all time dependent RTEMS actions. For example, calling `rtems_clock_tick` ten times per second yields a higher resolution than calling `rtems_clock_tick` two times per second. The `rtems_clock_tick` directive is responsible for maintaining both calendar time and the dynamic set of timers.

7.3.2 Setting the Time

The `rtems_clock_set` directive allows a task or an ISR to set the date and time maintained by RTEMS. If setting the date and time causes any outstanding timers to pass their deadline, then the expired timers will be fired during the invocation of the `rtems_clock_set` directive.

7.3.3 Obtaining the Time

The `rtems_clock_get` directive allows a task or an ISR to obtain the current date and time or date and time related information. The current date and time can be returned in either native or UNIX-style format. Additionally, the application can obtain date and time related information such as the number of seconds since the RTEMS epoch, the number of ticks since the executive was initialized, and the number of ticks per second. The information returned by the `rtems_clock_get` directive is dependent on the option selected by the caller. This is specified using one of the following constants associated with the enumerated type `rtems_clock_get_options`:

- `RTEMS_CLOCK_GET_TOD` - obtain native style date and time
- `RTEMS_CLOCK_GET_TIME_VALUE` - obtain UNIX-style date and time
- `RTEMS_CLOCK_GET_TICKS_SINCE_BOOT` - obtain number of ticks since RTEMS was initialized
- `RTEMS_CLOCK_GET_SECONDS_SINCE_EPOCH` - obtain number of seconds since RTEMS epoch
- `RTEMS_CLOCK_GET_TICKS_PER_SECOND` - obtain number of clock ticks per second

Calendar time operations will return an error code if invoked before the date and time have been set.

7.4 Directives

This section details the clock manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

7.4.1 CLOCK_SET - Set date and time

CALLING SEQUENCE:

```
rtems_status_code rtems_clock_set(  
    rtems_time_of_day *time_buffer  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - date and time set successfully

RTEMS_INVALID_ADDRESS - `time_buffer` is NULL

RTEMS_INVALID_CLOCK - invalid time of day

DESCRIPTION:

This directive sets the system date and time. The date, time, and ticks in the `time_buffer` structure are all range-checked, and an error is returned if any one is out of its valid range.

NOTES:

Years before 1988 are invalid.

The system date and time are based on the configured tick rate (number of microseconds in a tick).

Setting the time forward may cause a higher priority task, blocked waiting on a specific time, to be made ready. In this case, the calling task will be preempted after the next clock tick.

Re-initializing RTEMS causes the system date and time to be reset to an uninitialized state. Another call to `rtems_clock_set` is required to re-initialize the system date and time to application specific specifications.

7.4.2 CLOCK_GET - Get date and time information

CALLING SEQUENCE:

```
rtems_status_code rtems_clock_get(  
    rtems_clock_get_options option,  
    void *time_buffer  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - current time obtained successfully

RTEMS_NOT_DEFINED - system date and time is not set

RTEMS_INVALID_ADDRESS - `time_buffer` is NULL

DESCRIPTION:

This directive obtains the system date and time. If the caller is attempting to obtain the date and time (i.e. `option` is set to either `RTEMS_CLOCK_GET_SECONDS_SINCE_EPOCH`, `RTEMS_CLOCK_GET_TOD`, or `RTEMS_CLOCK_GET_TIME_VALUE`) and the date and time has not been set with a previous call to `rtems_clock_set`, then the `RTEMS_NOT_DEFINED` status code is returned. The caller can always obtain the number of ticks per second (`option` is `RTEMS_CLOCK_GET_TICKS_PER_SECOND`) and the number of ticks since the executive was initialized (`option` is `RTEMS_CLOCK_GET_TICKS_SINCE_BOOT`).

The `option` argument may taken on any value of the enumerated type `rtems_clock_get_options`. The data type expected for `time_buffer` is based on the value of `option` as indicated below:

- `RTEMS_CLOCK_GET_TOD` - (`rtems_time_of_day *`)
- `RTEMS_CLOCK_GET_SECONDS_SINCE_EPOCH` - (`rtems_interval *`)
- `RTEMS_CLOCK_GET_TICKS_SINCE_BOOT` - (`rtems_interval *`)
- `RTEMS_CLOCK_GET_TICKS_PER_SECOND` - (`rtems_interval *`)
- `RTEMS_CLOCK_GET_TIME_VALUE` - (`struct timeval *`)

NOTES:

This directive is callable from an ISR.

This directive will not cause the running task to be preempted. Re-initializing RTEMS causes the system date and time to be reset to an uninitialized state. Another call to `rtems_clock_set` is required to re-initialize the system date and time to application specific specifications.

7.4.3 CLOCK_GET_TOD - Get date and time in TOD format

CALLING SEQUENCE:

```
    rtems_status_code rtems_clock_get_tod(  
        rtems_time_of_day *time_buffer  
    );
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - current time obtained successfully

RTEMS_NOT_DEFINED - system date and time is not set

RTEMS_INVALID_ADDRESS - `time_buffer` is NULL

DESCRIPTION:

This directive obtains the system date and time. If the date and time has not been set with a previous call to `rtems_clock_set`, then the RTEMS_NOT_DEFINED status code is returned.

NOTES:

This directive is callable from an ISR.

This directive will not cause the running task to be preempted. Re-initializing RTEMS causes the system date and time to be reset to an uninitialized state. Another call to `rtems_clock_set` is required to re-initialize the system date and time to application specific specifications.

7.4.4 CLOCK_GET_TOD_TIMEVAL - Get date and time in timeval format

CALLING SEQUENCE:

```
rtems_status_code rtems_clock_get_tod(  
    struct timeval  *time  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - current time obtained successfully

RTEMS_NOT_DEFINED - system date and time is not set

RTEMS_INVALID_ADDRESS - time is NULL

DESCRIPTION:

This directive obtains the system date and time in POSIX `struct timeval` format. If the date and time has not been set with a previous call to `rtems_clock_set`, then the RTEMS_NOT_DEFINED status code is returned.

NOTES:

This directive is callable from an ISR.

This directive will not cause the running task to be preempted. Re-initializing RTEMS causes the system date and time to be reset to an uninitialized state. Another call to `rtems_clock_set` is required to re-initialize the system date and time to application specific specifications.

7.4.5 CLOCK_GET_SECONDS_SINCE_EPOCH - Get seconds since epoch

CALLING SEQUENCE:

```
rtcms_status_code rtcms_clock_get_seconds_since_epoch(  
    rtcms_interval *the_interval  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - current time obtained successfully

RTEMS_NOT_DEFINED - system date and time is not set

RTEMS_INVALID_ADDRESS - the_interval is NULL

DESCRIPTION:

This directive returns the number of seconds since the RTEMS epoch and the current system date and time. If the date and time has not been set with a previous call to `rtcms_clock_set`, then the RTEMS_NOT_DEFINED status code is returned.

NOTES:

This directive is callable from an ISR.

This directive will not cause the running task to be preempted. Re-initializing RTEMS causes the system date and time to be reset to an uninitialized state. Another call to `rtcms_clock_set` is required to re-initialize the system date and time to application specific specifications.

7.4.6 CLOCK_GET_TICKS_PER_SECOND - Get ticks per second

CALLING SEQUENCE:

```
rtems_interval rtems_clock_get_ticks_per_second(void);
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive returns the number of clock ticks per second. This is strictly based upon the microseconds per clock tick that the application has configured.

NOTES:

This directive is callable from an ISR.

This directive will not cause the running task to be preempted. Re-initializing RTEMS causes the system date and time to be reset to an uninitialized state. Another call to `rtems_clock_set` is required to re-initialize the system date and time to application specific specifications.

7.4.7 CLOCK_GET_TICKS_SINCE_BOOT - Get ticks since boot

CALLING SEQUENCE:

```
rtems_interval rtems_clock_get_ticks_since_boot(void);
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive returns the number of clock ticks that have elapsed since the system was booted. This is the historical measure of uptime in an RTEMS system. The newer service `rtems_clock_get_uptime` is another and potentially more accurate way of obtaining similar information.

NOTES:

This directive is callable from an ISR.

This directive will not cause the running task to be preempted. Re-initializing RTEMS causes the system date and time to be reset to an uninitialized state. Another call to `rtems_clock_set` is required to re-initialize the system date and time to application specific specifications.

This directive simply returns the number of times the directive `rtems_clock_tick` has been invoked since the system was booted.

7.4.8 CLOCK_GET_UPTIME - Get the time since boot

CALLING SEQUENCE:

```
rtems_status_code rtems_clock_get_uptime(  
    struct timespec *uptime  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - clock tick processed successfully

RTEMS_INVALID_ADDRESS - `time_buffer` is NULL

DESCRIPTION:

This directive returns the seconds and nanoseconds since the system was booted. If the BSP supports nanosecond clock accuracy, the time reported will probably be different on every call.

NOTES:

This directive may be called from an ISR.

7.4.9 CLOCK_SET_NANOSECONDS_EXTENSION - Install the nanoseconds since last tick handler

CALLING SEQUENCE:

```
rtems_status_code rtems_clock_set_nanoseconds_extension(  
    rtems_nanoseconds_extension_routine routine  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - clock tick processed successfully

RTEMS_INVALID_ADDRESS - `time_buffer` is NULL

DESCRIPTION:

This directive is used by the Clock device driver to install the `routine` which will be invoked by the internal RTEMS method used to obtain a highly accurate time of day. It is usually called during the initialization of the driver.

When the `routine` is invoked, it will determine the number of nanoseconds which have elapsed since the last invocation of the `rtems_clock_tick` directive. It should do this as quickly as possible with as little impact as possible on the device used as a clock source.

NOTES:

This directive may be called from an ISR.

This directive is called as part of every service to obtain the current date and time as well as timestamps.

7.4.10 CLOCK_TICK - Announce a clock tick

CALLING SEQUENCE:

```
rtems_status_code rtems_clock_tick( void );
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - clock tick processed successfully

DESCRIPTION:

This directive announces to RTEMS that a system clock tick has occurred. The directive is usually called from the timer interrupt ISR of the local processor. This directive maintains the system date and time, decrements timers for delayed tasks, timeouts, rate monotonic periods, and implements timeslicing.

NOTES:

This directive is typically called from an ISR.

The `microseconds_per_tick` and `ticks_per_timeslice` parameters in the Configuration Table contain the number of microseconds per tick and number of ticks per timeslice, respectively.

8 Timer Manager

8.1 Introduction

The timer manager provides support for timer facilities. The directives provided by the timer manager are:

- `rtems_timer_create` - Create a timer
- `rtems_timer_ident` - Get ID of a timer
- `rtems_timer_cancel` - Cancel a timer
- `rtems_timer_delete` - Delete a timer
- `rtems_timer_fire_after` - Fire timer after interval
- `rtems_timer_fire_when` - Fire timer when specified
- `rtems_timer_initiate_server` - Initiate server for task-based timers
- `rtems_timer_server_fire_after` - Fire task-based timer after interval
- `rtems_timer_server_fire_when` - Fire task-based timer when specified
- `rtems_timer_reset` - Reset an interval timer

8.2 Background

8.2.1 Required Support

A clock tick is required to support the functionality provided by this manager.

8.2.2 Timers

A timer is an RTEMS object which allows the application to schedule operations to occur at specific times in the future. User supplied timer service routines are invoked by either the `rtems_clock_tick` directive or a special Timer Server task when the timer fires. Timer service routines may perform any operations or directives which normally would be performed by the application code which invoked the `rtems_clock_tick` directive.

The timer can be used to implement watchdog routines which only fire to denote that an application error has occurred. The timer is reset at specific points in the application to ensure that the watchdog does not fire. Thus, if the application does not reset the watchdog timer, then the timer service routine will fire to indicate that the application has failed to reach a reset point. This use of a timer is sometimes referred to as a "keep alive" or a "deadman" timer.

8.2.3 Timer Server

The Timer Server task is responsible for executing the timer service routines associated with all task-based timers. This task executes at a priority higher than any RTEMS application task, and is created non-preemptible, and thus can be viewed logically as the lowest priority interrupt.

By providing a mechanism where timer service routines execute in task rather than interrupt space, the application is allowed a bit more flexibility in what operations a timer service

routine can perform. For example, the Timer Server can be configured to have a floating point context in which case it would be safe to perform floating point operations from a task-based timer. Most of the time, executing floating point instructions from an interrupt service routine is not considered safe. However, since the Timer Server task is non-preemptible, only directives allowed from an ISR can be called in the timer service routine.

The Timer Server is designed to remain blocked until a task-based timer fires. This reduces the execution overhead of the Timer Server.

8.2.4 Timer Service Routines

The timer service routine should adhere to C calling conventions and have a prototype similar to the following:

```
rtems_timer_service_routine user_routine(  
    rtems_id    timer_id,  
    void        *user_data  
);
```

Where the `timer_id` parameter is the RTEMS object ID of the timer which is being fired and `user_data` is a pointer to user-defined information which may be utilized by the timer service routine. The argument `user_data` may be NULL.

8.3 Operations

8.3.1 Creating a Timer

The `rtems_timer_create` directive creates a timer by allocating a Timer Control Block (TMCB), assigning the timer a user-specified name, and assigning it a timer ID. Newly created timers do not have a timer service routine associated with them and are not active.

8.3.2 Obtaining Timer IDs

When a timer is created, RTEMS generates a unique timer ID and assigns it to the created timer until it is deleted. The timer ID may be obtained by either of two methods. First, as the result of an invocation of the `rtems_timer_create` directive, the timer ID is stored in a user provided location. Second, the timer ID may be obtained later using the `rtems_timer_ident` directive. The timer ID is used by other directives to manipulate this timer.

8.3.3 Initiating an Interval Timer

The `rtems_timer_fire_after` and `rtems_timer_server_fire_after` directives initiate a timer to fire a user provided timer service routine after the specified number of clock ticks have elapsed. When the interval has elapsed, the timer service routine will be invoked from the `rtems_clock_tick` directive if it was initiated by the `rtems_timer_fire_after` directive and from the Timer Server task if initiated by the `rtems_timer_server_fire_after` directive.

8.3.4 Initiating a Time of Day Timer

The `rtems_timer_fire_when` and `rtems_timer_server_fire_when` directive initiate a timer to fire a user provided timer service routine when the specified time of day has been reached. When the interval has elapsed, the timer service routine will be invoked from the

`rtems_clock_tick` directive by the `rtems_timer_fire_when` directive and from the Timer Server task if initiated by the `rtems_timer_server_fire_when` directive.

8.3.5 Canceling a Timer

The `rtems_timer_cancel` directive is used to halt the specified timer. Once canceled, the timer service routine will not fire unless the timer is reinitiated. The timer can be reinitiated using the `rtems_timer_reset`, `rtems_timer_fire_after`, and `rtems_timer_fire_when` directives.

8.3.6 Resetting a Timer

The `rtems_timer_reset` directive is used to restore an interval timer initiated by a previous invocation of `rtems_timer_fire_after` or `rtems_timer_server_fire_after` to its original interval length. If the timer has not been used or the last usage of this timer was by the `rtems_timer_fire_when` or `rtems_timer_server_fire_when` directive, then an error is returned. The timer service routine is not changed or fired by this directive.

8.3.7 Initiating the Timer Server

The `rtems_timer_initiate_server` directive is used to allocate and start the execution of the Timer Server task. The application can specify both the stack size and attributes of the Timer Server. The Timer Server executes at a priority higher than any application task and thus the user can expect to be preempted as the result of executing the `rtems_timer_initiate_server` directive.

8.3.8 Deleting a Timer

The `rtems_timer_delete` directive is used to delete a timer. If the timer is running and has not expired, the timer is automatically canceled. The timer's control block is returned to the TMCB free list when it is deleted. A timer can be deleted by a task other than the task which created the timer. Any subsequent references to the timer's name and ID are invalid.

8.4 Directives

This section details the timer manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

8.4.1 TIMER_CREATE - Create a timer

CALLING SEQUENCE:

```
rtcms_status_code rtcms_timer_create(  
    rtcms_name  name,  
    rtcms_id    *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - timer created successfully

RTEMS_INVALID_ADDRESS - id is NULL

RTEMS_INVALID_NAME - invalid timer name

RTEMS_TOO_MANY - too many timers created

DESCRIPTION:

This directive creates a timer. The assigned timer id is returned in id. This id is used to access the timer with other timer manager directives. For control and maintenance of the timer, RTEMS allocates a TMCB from the local TMCB free pool and initializes it.

NOTES:

This directive will not cause the calling task to be preempted.

8.4.2 TIMER_IDENT - Get ID of a timer

CALLING SEQUENCE:

```
rtcms_status_code rtcms_timer_ident(  
    rtcms_name  name,  
    rtcms_id    *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - timer identified successfully

RTEMS_INVALID_ADDRESS - id is NULL

RTEMS_INVALID_NAME - timer name not found

DESCRIPTION:

This directive obtains the timer id associated with the timer name to be acquired. If the timer name is not unique, then the timer id will match one of the timers with that name. However, this timer id is not guaranteed to correspond to the desired timer. The timer id is used to access this timer in other timer related directives.

NOTES:

This directive will not cause the running task to be preempted.

8.4.3 TIMER_CANCEL - Cancel a timer

CALLING SEQUENCE:

```
rtems_status_code rtems_timer_cancel(  
    rtems_id id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - timer canceled successfully

RTEMS_INVALID_ID - invalid timer id

DESCRIPTION:

This directive cancels the timer id. This timer will be reinitiated by the next invocation of `rtems_timer_reset`, `rtems_timer_fire_after`, or `rtems_timer_fire_when` with this id.

NOTES:

This directive will not cause the running task to be preempted.

8.4.4 TIMER_DELETE - Delete a timer

CALLING SEQUENCE:

```
rtcms_status_code rtcms_timer_delete(  
    rtcms_id id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - timer deleted successfully

RTEMS_INVALID_ID - invalid timer id

DESCRIPTION:

This directive deletes the timer specified by id. If the timer is running, it is automatically canceled. The TMCB for the deleted timer is reclaimed by RTEMS.

NOTES:

This directive will not cause the running task to be preempted.

A timer can be deleted by a task other than the task which created the timer.

8.4.5 TIMER_FIRE_AFTER - Fire timer after interval

CALLING SEQUENCE:

```
rtcms_status_code rtcms_timer_fire_after(  
    rtcms_id          id,  
    rtcms_interval    ticks,  
    rtcms_timer_service_routine_entry routine,  
    void              *user_data  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - timer initiated successfully

RTEMS_INVALID_ADDRESS - routine is NULL

RTEMS_INVALID_ID - invalid timer id

RTEMS_INVALID_NUMBER - invalid interval

DESCRIPTION:

This directive initiates the timer specified by id. If the timer is running, it is automatically canceled before being initiated. The timer is scheduled to fire after an interval ticks clock ticks has passed. When the timer fires, the timer service routine routine will be invoked with the argument user_data.

NOTES:

This directive will not cause the running task to be preempted.

8.4.6 TIMER_FIRE_WHEN - Fire timer when specified

CALLING SEQUENCE:

```
rtems_status_code rtems_timer_fire_when(  
    rtems_id          id,  
    rtems_time_of_day *wall_time,  
    rtems_timer_service_routine_entry routine,  
    void              *user_data  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - timer initiated successfully

RTEMS_INVALID_ADDRESS - routine is NULL

RTEMS_INVALID_ADDRESS - wall_time is NULL

RTEMS_INVALID_ID - invalid timer id

RTEMS_NOT_DEFINED - system date and time is not set

RTEMS_INVALID_CLOCK - invalid time of day

DESCRIPTION:

This directive initiates the timer specified by id. If the timer is running, it is automatically canceled before being initiated. The timer is scheduled to fire at the time of day specified by wall_time. When the timer fires, the timer service routine routine will be invoked with the argument user_data.

NOTES:

This directive will not cause the running task to be preempted.

8.4.7 TIMER_INITIATE_SERVER - Initiate server for task-based timers

CALLING SEQUENCE:

```
rtems_status_code rtems_timer_initiate_server(  
    uint32_t      priority,  
    uint32_t      stack_size,  
    rtems_attribute attribute_set  
)  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - Timer Server initiated successfully

RTEMS_TOO_MANY - too many tasks created

DESCRIPTION:

This directive initiates the Timer Server task. This task is responsible for executing all timers initiated via the `rtems_timer_server_fire_after` or `rtems_timer_server_fire_when` directives.

NOTES:

This directive could cause the calling task to be preempted.

The Timer Server task is created using the `rtems_task_create` service and must be accounted for when configuring the system.

Even though this directive invokes the `rtems_task_create` and `rtems_task_start` directives, it should only fail due to resource allocation problems.

8.4.8 TIMER_SERVER_FIRE_AFTER - Fire task-based timer after interval

CALLING SEQUENCE:

```
rtms_status_code rtms_timer_server_fire_after(  
    rtms_id          id,  
    rtms_interval    ticks,  
    rtms_timer_service_routine_entry routine,  
    void             *user_data  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - timer initiated successfully

RTEMS_INVALID_ADDRESS - routine is NULL

RTEMS_INVALID_ID - invalid timer id

RTEMS_INVALID_NUMBER - invalid interval

RTEMS_INCORRECT_STATE - Timer Server not initiated

DESCRIPTION:

This directive initiates the timer specified by id and specifies that when it fires it will be executed by the Timer Server.

If the timer is running, it is automatically canceled before being initiated. The timer is scheduled to fire after an interval ticks clock ticks has passed. When the timer fires, the timer service routine routine will be invoked with the argument user_data.

NOTES:

This directive will not cause the running task to be preempted.

8.4.9 TIMER_SERVER_FIRE_WHEN - Fire task-based timer when specified

CALLING SEQUENCE:

```
rtcms_status_code rtcms_timer_server_fire_when(  
    rtcms_id          id,  
    rtcms_time_of_day *wall_time,  
    rtcms_timer_service_routine_entry routine,  
    void              *user_data  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - timer initiated successfully
RTEMS_INVALID_ADDRESS - routine is NULL
RTEMS_INVALID_ADDRESS - wall_time is NULL
RTEMS_INVALID_ID - invalid timer id
RTEMS_NOT_DEFINED - system date and time is not set
RTEMS_INVALID_CLOCK - invalid time of day
RTEMS_INCORRECT_STATE - Timer Server not initiated

DESCRIPTION:

This directive initiates the timer specified by id and specifies that when it fires it will be executed by the Timer Server.

If the timer is running, it is automatically canceled before being initiated. The timer is scheduled to fire at the time of day specified by wall_time. When the timer fires, the timer service routine routine will be invoked with the argument user_data.

NOTES:

This directive will not cause the running task to be preempted.

8.4.10 TIMER_RESET - Reset an interval timer

CALLING SEQUENCE:

```
rtems_status_code rtems_timer_reset(  
    rtems_id    id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - timer reset successfully

RTEMS_INVALID_ID - invalid timer id

RTEMS_NOT_DEFINED - attempted to reset a when or newly created timer

DESCRIPTION:

This directive resets the timer associated with `id`. This timer must have been previously initiated with either the `rtems_timer_fire_after` or `rtems_timer_server_fire_after` directive. If active the timer is canceled, after which the timer is reinitiated using the same interval and timer service routine which the original `rtems_timer_fire_after` or `rtems_timer_server_fire_after` directive used.

NOTES:

If the timer has not been used or the last usage of this timer was by a `rtems_timer_fire_when` or `rtems_timer_server_fire_when` directive, then the `RTEMS_NOT_DEFINED` error is returned.

Restarting a cancelled after timer results in the timer being reinitiated with its previous timer service routine and interval.

This directive will not cause the running task to be preempted.

9 Semaphore Manager

9.1 Introduction

The semaphore manager utilizes standard Dijkstra counting semaphores to provide synchronization and mutual exclusion capabilities. The directives provided by the semaphore manager are:

- `rtems_semaphore_create` - Create a semaphore
- `rtems_semaphore_ident` - Get ID of a semaphore
- `rtems_semaphore_delete` - Delete a semaphore
- `rtems_semaphore_obtain` - Acquire a semaphore
- `rtems_semaphore_release` - Release a semaphore
- `rtems_semaphore_flush` - Unblock all tasks waiting on a semaphore

9.2 Background

A semaphore can be viewed as a protected variable whose value can be modified only with the `rtems_semaphore_create`, `rtems_semaphore_obtain`, and `rtems_semaphore_release` directives. RTEMS supports both binary and counting semaphores. A binary semaphore is restricted to values of zero or one, while a counting semaphore can assume any non-negative integer value.

A binary semaphore can be used to control access to a single resource. In particular, it can be used to enforce mutual exclusion for a critical section in user code. In this instance, the semaphore would be created with an initial count of one to indicate that no task is executing the critical section of code. Upon entry to the critical section, a task must issue the `rtems_semaphore_obtain` directive to prevent other tasks from entering the critical section. Upon exit from the critical section, the task must issue the `rtems_semaphore_release` directive to allow another task to execute the critical section.

A counting semaphore can be used to control access to a pool of two or more resources. For example, access to three printers could be administered by a semaphore created with an initial count of three. When a task requires access to one of the printers, it issues the `rtems_semaphore_obtain` directive to obtain access to a printer. If a printer is not currently available, the task can wait for a printer to become available or return immediately. When the task has completed printing, it should issue the `rtems_semaphore_release` directive to allow other tasks access to the printer.

Task synchronization may be achieved by creating a semaphore with an initial count of zero. One task waits for the arrival of another task by issuing a `rtems_semaphore_obtain` directive when it reaches a synchronization point. The other task performs a corresponding `rtems_semaphore_release` operation when it reaches its synchronization point, thus unblocking the pending task.

9.2.1 Nested Resource Access

Deadlock occurs when a task owning a binary semaphore attempts to acquire that same semaphore and blocks as result. Since the semaphore is allocated to a task, it cannot be

deleted. Therefore, the task that currently holds the semaphore and is also blocked waiting for that semaphore will never execute again.

RTEMS addresses this problem by allowing the task holding the binary semaphore to obtain the same binary semaphore multiple times in a nested manner. Each `rtems_semaphore_obtain` must be accompanied with a `rtems_semaphore_release`. The semaphore will only be made available for acquisition by other tasks when the outermost `rtems_semaphore_obtain` is matched with a `rtems_semaphore_release`.

Simple binary semaphores do not allow nested access and so can be used for task synchronization.

9.2.2 Priority Inversion

Priority inversion is a form of indefinite postponement which is common in multitasking, preemptive executives with shared resources. Priority inversion occurs when a high priority task requests access to shared resource which is currently allocated to low priority task. The high priority task must block until the low priority task releases the resource. This problem is exacerbated when the low priority task is prevented from executing by one or more medium priority tasks. Because the low priority task is not executing, it cannot complete its interaction with the resource and release that resource. The high priority task is effectively prevented from executing by lower priority tasks.

9.2.3 Priority Inheritance

Priority inheritance is an algorithm that calls for the lower priority task holding a resource to have its priority increased to that of the highest priority task blocked waiting for that resource. Each time a task blocks attempting to obtain the resource, the task holding the resource may have its priority increased.

RTEMS supports priority inheritance for local, binary semaphores that use the priority task wait queue blocking discipline. When a task of higher priority than the task holding the semaphore blocks, the priority of the task holding the semaphore is increased to that of the blocking task. When the task holding the task completely releases the binary semaphore (i.e. not for a nested release), the holder's priority is restored to the value it had before any higher priority was inherited.

The RTEMS implementation of the priority inheritance algorithm takes into account the scenario in which a task holds more than one binary semaphore. The holding task will execute at the priority of the higher of the highest ceiling priority or at the priority of the highest priority task blocked waiting for any of the semaphores the task holds. Only when the task releases ALL of the binary semaphores it holds will its priority be restored to the normal value.

9.2.4 Priority Ceiling

Priority ceiling is an algorithm that calls for the lower priority task holding a resource to have its priority increased to that of the highest priority task which will EVER block waiting for that resource. This algorithm addresses the problem of priority inversion although it avoids the possibility of changing the priority of the task holding the resource multiple times. The priority ceiling algorithm will only change the priority of the task holding the

resource a maximum of one time. The ceiling priority is set at creation time and must be the priority of the highest priority task which will ever attempt to acquire that semaphore.

RTEMS supports priority ceiling for local, binary semaphores that use the priority task wait queue blocking discipline. When a task of lower priority than the ceiling priority successfully obtains the semaphore, its priority is raised to the ceiling priority. When the task holding the task completely releases the binary semaphore (i.e. not for a nested release), the holder's priority is restored to the value it had before any higher priority was put into effect.

The need to identify the highest priority task which will attempt to obtain a particular semaphore can be a difficult task in a large, complicated system. Although the priority ceiling algorithm is more efficient than the priority inheritance algorithm with respect to the maximum number of task priority changes which may occur while a task holds a particular semaphore, the priority inheritance algorithm is more forgiving in that it does not require this apriori information.

The RTEMS implementation of the priority ceiling algorithm takes into account the scenario in which a task holds more than one binary semaphore. The holding task will execute at the priority of the higher of the highest ceiling priority or at the priority of the highest priority task blocked waiting for any of the semaphores the task holds. Only when the task releases ALL of the binary semaphores it holds will its priority be restored to the normal value.

9.2.5 Building a Semaphore Attribute Set

In general, an attribute set is built by a bitwise OR of the desired attribute components. The following table lists the set of valid semaphore attributes:

- RTEMS_FIFO - tasks wait by FIFO (default)
- RTEMS_PRIORITY - tasks wait by priority
- RTEMS_BINARY_SEMAPHORE - restrict values to 0 and 1
- RTEMS_COUNTING_SEMAPHORE - no restriction on values (default)
- RTEMS_SIMPLE_BINARY_SEMAPHORE - restrict values to 0 and 1, do not allow nested access, allow deletion of locked semaphore.
- RTEMS_NO_INHERIT_PRIORITY - do not use priority inheritance (default)
- RTEMS_INHERIT_PRIORITY - use priority inheritance
- RTEMS_PRIORITY_CEILING - use priority ceiling
- RTEMS_NO_PRIORITY_CEILING - do not use priority ceiling (default)
- RTEMS_LOCAL - local task (default)
- RTEMS_GLOBAL - global task

Attribute values are specifically designed to be mutually exclusive, therefore bitwise OR and addition operations are equivalent as long as each attribute appears exactly once in the component list. An attribute listed as a default is not required to appear in the attribute list, although it is a good programming practice to specify default attributes. If all defaults are desired, the attribute `RTEMS_DEFAULT_ATTRIBUTES` should be specified on this call.

This example demonstrates the `attribute_set` parameter needed to create a local semaphore with the task priority waiting queue discipline. The `attribute_set` parameter passed to the `rtems_semaphore_create` directive could be either `RTEMS_PRIORITY` or `RTEMS_LOCAL`

| RTEMS_PRIORITY. The attribute_set parameter can be set to RTEMS_PRIORITY because RTEMS_LOCAL is the default for all created tasks. If a similar semaphore were to be known globally, then the attribute_set parameter would be RTEMS_GLOBAL | RTEMS_PRIORITY.

Some combinations of these attributes are invalid. For example, priority ordered blocking discipline must be applied to a binary semaphore in order to use either the priority inheritance or priority ceiling functionality. The following tree figure illustrates the valid combinations.

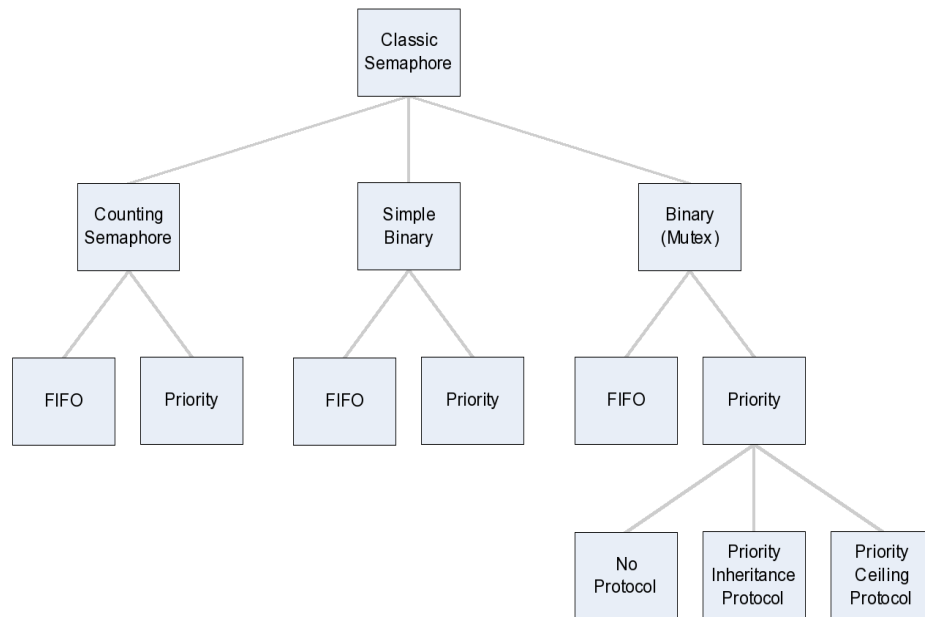

Figure 9.1: Valid Semaphore Attributes Combinations

9.2.6 Building a SEMAPHORE_OBTAIN Option Set

In general, an option is built by a bitwise OR of the desired option components. The set of valid options for the `rtems_semaphore_obtain` directive are listed in the following table:

- RTEMS_WAIT - task will wait for semaphore (default)
- RTEMS_NO_WAIT - task should not wait

Option values are specifically designed to be mutually exclusive, therefore bitwise OR and addition operations are equivalent as long as each attribute appears exactly once in the component list. An option listed as a default is not required to appear in the list, although it is a good programming practice to specify default options. If all defaults are desired, the option RTEMS_DEFAULT_OPTIONS should be specified on this call.

This example demonstrates the option parameter needed to poll for a semaphore. The option parameter passed to the `rtems_semaphore_obtain` directive should be `RTEMS_NO_WAIT`.

9.3 Operations

9.3.1 Creating a Semaphore

The `rtems_semaphore_create` directive creates a binary or counting semaphore with a user-specified name as well as an initial count. If a binary semaphore is created with a count of zero (0) to indicate that it has been allocated, then the task creating the semaphore is considered the current holder of the semaphore. At create time the method for ordering waiting tasks in the semaphore's task wait queue (by FIFO or task priority) is specified. Additionally, the priority inheritance or priority ceiling algorithm may be selected for local, binary semaphores that use the priority task wait queue blocking discipline. If the priority ceiling algorithm is selected, then the highest priority of any task which will attempt to obtain this semaphore must be specified. RTEMS allocates a Semaphore Control Block (SCB) from the SCB free list. This data structure is used by RTEMS to manage the newly created semaphore. Also, a unique semaphore ID is generated and returned to the calling task.

9.3.2 Obtaining Semaphore IDs

When a semaphore is created, RTEMS generates a unique semaphore ID and assigns it to the created semaphore until it is deleted. The semaphore ID may be obtained by either of two methods. First, as the result of an invocation of the `rtems_semaphore_create` directive, the semaphore ID is stored in a user provided location. Second, the semaphore ID may be obtained later using the `rtems_semaphore_ident` directive. The semaphore ID is used by other semaphore manager directives to access this semaphore.

9.3.3 Acquiring a Semaphore

The `rtems_semaphore_obtain` directive is used to acquire the specified semaphore. A simplified version of the `rtems_semaphore_obtain` directive can be described as follows:

```
if semaphore's count is greater than zero
    then decrement semaphore's count
    else wait for release of semaphore

return SUCCESSFUL
```

When the semaphore cannot be immediately acquired, one of the following situations applies:

- By default, the calling task will wait forever to acquire the semaphore.
- Specifying `RTEMS_NO_WAIT` forces an immediate return with an error status code.
- Specifying a timeout limits the interval the task will wait before returning with an error status code.

If the task waits to acquire the semaphore, then it is placed in the semaphore's task wait queue in either FIFO or task priority order. If the task blocked waiting for a binary

semaphore using priority inheritance and the task's priority is greater than that of the task currently holding the semaphore, then the holding task will inherit the priority of the blocking task. All tasks waiting on a semaphore are returned an error code when the semaphore is deleted.

When a task successfully obtains a semaphore using priority ceiling and the priority ceiling for this semaphore is greater than that of the holder, then the holder's priority will be elevated.

9.3.4 Releasing a Semaphore

The `rtems_semaphore_release` directive is used to release the specified semaphore. A simplified version of the `rtems_semaphore_release` directive can be described as follows:

```
if no tasks are waiting on this semaphore
    then increment semaphore's count
    else assign semaphore to a waiting task

return SUCCESSFUL
```

If this is the outermost release of a binary semaphore that uses priority inheritance or priority ceiling and the task does not currently hold any other binary semaphores, then the task performing the `rtems_semaphore_release` will have its priority restored to its normal value.

9.3.5 Deleting a Semaphore

The `rtems_semaphore_delete` directive removes a semaphore from the system and frees its control block. A semaphore can be deleted by any local task that knows the semaphore's ID. As a result of this directive, all tasks blocked waiting to acquire the semaphore will be readied and returned a status code which indicates that the semaphore was deleted. Any subsequent references to the semaphore's name and ID are invalid.

9.4 Directives

This section details the semaphore manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

9.4.1 SEMAPHORE_CREATE - Create a semaphore

CALLING SEQUENCE:

```

rtems_status_code rtems_semaphore_create(
    rtems_name      name,
    uint32_t        count,
    rtems_attribute  attribute_set,
    rtems_task_priority priority_ceiling,
    rtems_id        *id
);

```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - semaphore created successfully

RTEMS_INVALID_NAME - invalid semaphore name

RTEMS_INVALID_ADDRESS - id is NULL

RTEMS_TOO_MANY - too many semaphores created

RTEMS_NOT_DEFINED - invalid attribute set

RTEMS_INVALID_NUMBER - invalid starting count for binary semaphore

RTEMS_MP_NOT_CONFIGURED - multiprocessing not configured

RTEMS_TOO_MANY - too many global objects

DESCRIPTION:

This directive creates a semaphore which resides on the local node. The created semaphore has the user-defined name specified in name and the initial count specified in count. For control and maintenance of the semaphore, RTEMS allocates and initializes a SMCB. The RTEMS-assigned semaphore id is returned in id. This semaphore id is used with other semaphore related directives to access the semaphore.

Specifying PRIORITY in attribute_set causes tasks waiting for a semaphore to be serviced according to task priority. When FIFO is selected, tasks are serviced in First In-First Out order.

NOTES:

This directive will not cause the calling task to be preempted.

The priority inheritance and priority ceiling algorithms are only supported for local, binary semaphores that use the priority task wait queue blocking discipline.

The following semaphore attribute constants are defined by RTEMS:

- RTEMS_FIFO - tasks wait by FIFO (default)
- RTEMS_PRIORITY - tasks wait by priority
- RTEMS_BINARY_SEMAPHORE - restrict values to 0 and 1
- RTEMS_COUNTING_SEMAPHORE - no restriction on values (default)
- RTEMS_SIMPLE_BINARY_SEMAPHORE - restrict values to 0 and 1, block on nested access, allow deletion of locked semaphore.
- RTEMS_NO_INHERIT_PRIORITY - do not use priority inheritance (default)

- RTEMS_INHERIT_PRIORITY - use priority inheritance
- RTEMS_PRIORITY_CEILING - use priority ceiling
- RTEMS_NO_PRIORITY_CEILING - do not use priority ceiling (default)
- RTEMS_LOCAL - local semaphore (default)
- RTEMS_GLOBAL - global semaphore

Semaphores should not be made global unless remote tasks must interact with the created semaphore. This is to avoid the system overhead incurred by the creation of a global semaphore. When a global semaphore is created, the semaphore's name and id must be transmitted to every node in the system for insertion in the local copy of the global object table.

Note that some combinations of attributes are not valid. See the earlier discussion on this.

The total number of global objects, including semaphores, is limited by the `maximum_global_objects` field in the Configuration Table.

9.4.2 SEMAPHORE_IDENT - Get ID of a semaphore

CALLING SEQUENCE:

```
rtcms_status_code rtcms_semaphore_ident(  
    rtcms_name  name,  
    uint32_t    node,  
    rtcms_id    *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - semaphore identified successfully

RTEMS_INVALID_NAME - semaphore name not found

RTEMS_INVALID_NODE - invalid node id

DESCRIPTION:

This directive obtains the semaphore id associated with the semaphore name. If the semaphore name is not unique, then the semaphore id will match one of the semaphores with that name. However, this semaphore id is not guaranteed to correspond to the desired semaphore. The semaphore id is used by other semaphore related directives to access the semaphore.

NOTES:

This directive will not cause the running task to be preempted.

If node is RTEMS_SEARCH_ALL_NODES, all nodes are searched with the local node being searched first. All other nodes are searched with the lowest numbered node searched first.

If node is a valid node number which does not represent the local node, then only the semaphores exported by the designated node are searched.

This directive does not generate activity on remote nodes. It accesses only the local copy of the global object table.

9.4.3 SEMAPHORE_DELETE - Delete a semaphore

CALLING SEQUENCE:

```
rtcms_status_code rtcms_semaphore_delete(  
    rtcms_id id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - semaphore deleted successfully

RTEMS_INVALID_ID - invalid semaphore id

RTEMS_ILLEGAL_ON_REMOTE_OBJECT - cannot delete remote semaphore

RTEMS_RESOURCE_IN_USE - binary semaphore is in use

DESCRIPTION:

This directive deletes the semaphore specified by `id`. All tasks blocked waiting to acquire the semaphore will be readied and returned a status code which indicates that the semaphore was deleted. The SMCB for this semaphore is reclaimed by RTEMS.

NOTES:

The calling task will be preempted if it is enabled by the task's execution mode and a higher priority local task is waiting on the deleted semaphore. The calling task will NOT be preempted if all of the tasks that are waiting on the semaphore are remote tasks.

The calling task does not have to be the task that created the semaphore. Any local task that knows the semaphore id can delete the semaphore.

When a global semaphore is deleted, the semaphore id must be transmitted to every node in the system for deletion from the local copy of the global object table.

The semaphore must reside on the local node, even if the semaphore was created with the `RTEMS_GLOBAL` option.

Proxies, used to represent remote tasks, are reclaimed when the semaphore is deleted.

9.4.4 SEMAPHORE_OBTAIN - Acquire a semaphore

CALLING SEQUENCE:

```
rtems_status_code rtems_semaphore_obtain(  
    rtems_id      id,  
    rtems_option   option_set,  
    rtems_interval timeout  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - semaphore obtained successfully

RTEMS_UNSATISFIED - semaphore not available

RTEMS_TIMEOUT - timed out waiting for semaphore

RTEMS_OBJECT_WAS_DELETED - semaphore deleted while waiting

RTEMS_INVALID_ID - invalid semaphore id

DESCRIPTION:

This directive acquires the semaphore specified by `id`. The `RTEMS_WAIT` and `RTEMS_NO_WAIT` components of the options parameter indicate whether the calling task wants to wait for the semaphore to become available or return immediately if the semaphore is not currently available. With either `RTEMS_WAIT` or `RTEMS_NO_WAIT`, if the current semaphore count is positive, then it is decremented by one and the semaphore is successfully acquired by returning immediately with a successful return code.

If the calling task chooses to return immediately and the current semaphore count is zero or negative, then a status code is returned indicating that the semaphore is not available. If the calling task chooses to wait for a semaphore and the current semaphore count is zero or negative, then it is decremented by one and the calling task is placed on the semaphore's wait queue and blocked. If the semaphore was created with the `RTEMS_PRIORITY` attribute, then the calling task is inserted into the queue according to its priority. However, if the semaphore was created with the `RTEMS_FIFO` attribute, then the calling task is placed at the rear of the wait queue. If the binary semaphore was created with the `RTEMS_INHERIT_PRIORITY` attribute, then the priority of the task currently holding the binary semaphore is guaranteed to be greater than or equal to that of the blocking task. If the binary semaphore was created with the `RTEMS_PRIORITY_CEILING` attribute, a task successfully obtains the semaphore, and the priority of that task is greater than the ceiling priority for this semaphore, then the priority of the task obtaining the semaphore is elevated to that of the ceiling.

The timeout parameter specifies the maximum interval the calling task is willing to be blocked waiting for the semaphore. If it is set to `RTEMS_NO_TIMEOUT`, then the calling task will wait forever. If the semaphore is available or the `RTEMS_NO_WAIT` option component is set, then timeout is ignored.

NOTES:

The following semaphore acquisition option constants are defined by RTEMS:

- `RTEMS_WAIT` - task will wait for semaphore (default)

- `RTEMS_NO_WAIT` - task should not wait

Attempting to obtain a global semaphore which does not reside on the local node will generate a request to the remote node to access the semaphore. If the semaphore is not available and `RTEMS_NO_WAIT` was not specified, then the task must be blocked until the semaphore is released. A proxy is allocated on the remote node to represent the task until the semaphore is released.

A clock tick is required to support the timeout functionality of this directive.

9.4.5 SEMAPHORE_RELEASE - Release a semaphore

CALLING SEQUENCE:

```
    rtems_status_code rtems_semaphore_release(  
        rtems_id id  
    );
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - semaphore released successfully

RTEMS_INVALID_ID - invalid semaphore id

RTEMS_NOT_OWNER_OF_RESOURCE - calling task does not own semaphore

DESCRIPTION:

This directive releases the semaphore specified by id. The semaphore count is incremented by one. If the count is zero or negative, then the first task on this semaphore's wait queue is removed and unblocked. The unblocked task may preempt the running task if the running task's preemption mode is enabled and the unblocked task has a higher priority than the running task.

NOTES:

The calling task may be preempted if it causes a higher priority task to be made ready for execution.

Releasing a global semaphore which does not reside on the local node will generate a request telling the remote node to release the semaphore.

If the task to be unblocked resides on a different node from the semaphore, then the semaphore allocation is forwarded to the appropriate node, the waiting task is unblocked, and the proxy used to represent the task is reclaimed.

The outermost release of a local, binary, priority inheritance or priority ceiling semaphore may result in the calling task having its priority lowered. This will occur if the calling task holds no other binary semaphores and it has inherited a higher priority.

9.4.6 SEMAPHORE_FLUSH - Unblock all tasks waiting on a semaphore

CALLING SEQUENCE:

```
rtems_status_code rtems_semaphore_flush(  
    rtems_id id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - semaphore released successfully

RTEMS_INVALID_ID - invalid semaphore id

RTEMS_ILLEGAL_ON_REMOTE_OBJECT - not supported for remote semaphores

DESCRIPTION:

This directive unblocks all tasks waiting on the semaphore specified by id. Since there are tasks blocked on the semaphore, the semaphore's count is not changed by this directive and thus is zero before and after this directive is executed. Tasks which are unblocked as the result of this directive will return from the `rtems_semaphore_obtain` directive with a status code of `RTEMS_UNSATISFIED` to indicate that the semaphore was not obtained.

This directive may unblock any number of tasks. Any of the unblocked tasks may preempt the running task if the running task's preemption mode is enabled and an unblocked task has a higher priority than the running task.

NOTES:

The calling task may be preempted if it causes a higher priority task to be made ready for execution.

If the task to be unblocked resides on a different node from the semaphore, then the waiting task is unblocked, and the proxy used to represent the task is reclaimed.

10 Message Manager

10.1 Introduction

The message manager provides communication and synchronization capabilities using RTEMS message queues. The directives provided by the message manager are:

- `rtems_message_queue_create` - Create a queue
- `rtems_message_queue_ident` - Get ID of a queue
- `rtems_message_queue_delete` - Delete a queue
- `rtems_message_queue_send` - Put message at rear of a queue
- `rtems_message_queue_urgent` - Put message at front of a queue
- `rtems_message_queue_broadcast` - Broadcast N messages to a queue
- `rtems_message_queue_receive` - Receive message from a queue
- `rtems_message_queue_get_number_pending` - Get number of messages pending on a queue
- `rtems_message_queue_flush` - Flush all messages on a queue

10.2 Background

10.2.1 Messages

A message is a variable length buffer where information can be stored to support communication. The length of the message and the information stored in that message are user-defined and can be actual data, pointer(s), or empty.

10.2.2 Message Queues

A message queue permits the passing of messages among tasks and ISRs. Message queues can contain a variable number of messages. Normally messages are sent to and received from the queue in FIFO order using the `rtems_message_queue_send` directive. However, the `rtems_message_queue_urgent` directive can be used to place messages at the head of a queue in LIFO order.

Synchronization can be accomplished when a task can wait for a message to arrive at a queue. Also, a task may poll a queue for the arrival of a message.

The maximum length message which can be sent is set on a per message queue basis.

10.2.3 Building a Message Queue Attribute Set

In general, an attribute set is built by a bitwise OR of the desired attribute components. The set of valid message queue attributes is provided in the following table:

- `RTEMS_FIFO` - tasks wait by FIFO (default)
- `RTEMS_PRIORITY` - tasks wait by priority
- `RTEMS_LOCAL` - local message queue (default)
- `RTEMS_GLOBAL` - global message queue

An attribute listed as a default is not required to appear in the attribute list, although it is a good programming practice to specify default attributes. If all defaults are desired, the attribute `RTEMS_DEFAULT_ATTRIBUTES` should be specified on this call.

This example demonstrates the `attribute_set` parameter needed to create a local message queue with the task priority waiting queue discipline. The `attribute_set` parameter to the `rtems_message_queue_create` directive could be either `RTEMS_PRIORITY` or `RTEMS_LOCAL` | `RTEMS_PRIORITY`. The `attribute_set` parameter can be set to `RTEMS_PRIORITY` because `RTEMS_LOCAL` is the default for all created message queues. If a similar message queue were to be known globally, then the `attribute_set` parameter would be `RTEMS_GLOBAL` | `RTEMS_PRIORITY`.

10.2.4 Building a MESSAGE_QUEUE_RECEIVE Option Set

In general, an option is built by a bitwise OR of the desired option components. The set of valid options for the `rtems_message_queue_receive` directive are listed in the following table:

- `RTEMS_WAIT` - task will wait for a message (default)
- `RTEMS_NO_WAIT` - task should not wait

An option listed as a default is not required to appear in the option OR list, although it is a good programming practice to specify default options. If all defaults are desired, the option `RTEMS_DEFAULT_OPTIONS` should be specified on this call.

This example demonstrates the option parameter needed to poll for a message to arrive. The option parameter passed to the `rtems_message_queue_receive` directive should be `RTEMS_NO_WAIT`.

10.3 Operations

10.3.1 Creating a Message Queue

The `rtems_message_queue_create` directive creates a message queue with the user-defined name. The user specifies the maximum message size and maximum number of messages which can be placed in the message queue at one time. The user may select FIFO or task priority as the method for placing waiting tasks in the task wait queue. RTEMS allocates a Queue Control Block (QCB) from the QCB free list to maintain the newly created queue as well as memory for the message buffer pool associated with this message queue. RTEMS also generates a message queue ID which is returned to the calling task.

For GLOBAL message queues, the maximum message size is effectively limited to the longest message which the MPCP is capable of transmitting.

10.3.2 Obtaining Message Queue IDs

When a message queue is created, RTEMS generates a unique message queue ID. The message queue ID may be obtained by either of two methods. First, as the result of an invocation of the `rtems_message_queue_create` directive, the queue ID is stored in a user provided location. Second, the queue ID may be obtained later using the `rtems_message_queue_ident` directive. The queue ID is used by other message manager directives to access this message queue.

10.3.3 Receiving a Message

The `rtems_message_queue_receive` directive attempts to retrieve a message from the specified message queue. If at least one message is in the queue, then the message is removed from the queue, copied to the caller's message buffer, and returned immediately along with the length of the message. When messages are unavailable, one of the following situations applies:

- By default, the calling task will wait forever for the message to arrive.
- Specifying the `RTEMS_NO_WAIT` option forces an immediate return with an error status code.
- Specifying a timeout limits the period the task will wait before returning with an error status.

If the task waits for a message, then it is placed in the message queue's task wait queue in either FIFO or task priority order. All tasks waiting on a message queue are returned an error code when the message queue is deleted.

10.3.4 Sending a Message

Messages can be sent to a queue with the `rtems_message_queue_send` and `rtems_message_queue_urgent` directives. These directives work identically when tasks are waiting to receive a message. A task is removed from the task waiting queue, unblocked, and the message is copied to a waiting task's message buffer.

When no tasks are waiting at the queue, `rtems_message_queue_send` places the message at the rear of the message queue, while `rtems_message_queue_urgent` places the message at the front of the queue. The message is copied to a message buffer from this message queue's buffer pool and then placed in the message queue. Neither directive can successfully send a message to a message queue which has a full queue of pending messages.

10.3.5 Broadcasting a Message

The `rtems_message_queue_broadcast` directive sends the same message to every task waiting on the specified message queue as an atomic operation. The message is copied to each waiting task's message buffer and each task is unblocked. The number of tasks which were unblocked is returned to the caller.

10.3.6 Deleting a Message Queue

The `rtems_message_queue_delete` directive removes a message queue from the system and frees its control block as well as the memory associated with this message queue's message buffer pool. A message queue can be deleted by any local task that knows the message queue's ID. As a result of this directive, all tasks blocked waiting to receive a message from the message queue will be readied and returned a status code which indicates that the message queue was deleted. Any subsequent references to the message queue's name and ID are invalid. Any messages waiting at the message queue are also deleted and deallocated.

10.4 Directives

This section details the message manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

10.4.1 MESSAGE_QUEUE_CREATE - Create a queue

CALLING SEQUENCE:

```

rtems_status_code rtems_message_queue_create(
    rtems_name      name,
    uint32_t        count,
    size_t          max_message_size,
    rtems_attribute attribute_set,
    rtems_id        *id
);

```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - queue created successfully
 RTEMS_INVALID_NAME - invalid queue name
 RTEMS_INVALID_ADDRESS - id is NULL
 RTEMS_INVALID_NUMBER - invalid message count
 RTEMS_INVALID_SIZE - invalid message size
 RTEMS_TOO_MANY - too many queues created
 RTEMS_UNSATISFIED - unable to allocate message buffers
 RTEMS_MP_NOT_CONFIGURED - multiprocessing not configured
 RTEMS_TOO_MANY - too many global objects

DESCRIPTION:

This directive creates a message queue which resides on the local node with the user-defined name specified in name. For control and maintenance of the queue, RTEMS allocates and initializes a QCB. Memory is allocated from the RTEMS Workspace for the specified count of messages, each of max_message_size bytes in length. The RTEMS-assigned queue id, returned in id, is used to access the message queue.

Specifying RTEMS_PRIORITY in attribute_set causes tasks waiting for a message to be serviced according to task priority. When RTEMS_FIFO is specified, waiting tasks are serviced in First In-First Out order.

NOTES:

This directive will not cause the calling task to be preempted.

The following message queue attribute constants are defined by RTEMS:

- RTEMS_FIFO - tasks wait by FIFO (default)
- RTEMS_PRIORITY - tasks wait by priority
- RTEMS_LOCAL - local message queue (default)
- RTEMS_GLOBAL - global message queue

Message queues should not be made global unless remote tasks must interact with the created message queue. This is to avoid the system overhead incurred by the creation of a global message queue. When a global message queue is created, the message queue's name and id must be transmitted to every node in the system for insertion in the local copy of the global object table.

For GLOBAL message queues, the maximum message size is effectively limited to the longest message which the MPCU is capable of transmitting.

The total number of global objects, including message queues, is limited by the `maximum_global_objects` field in the configuration table.

10.4.2 MESSAGE_QUEUE_IDENT - Get ID of a queue

CALLING SEQUENCE:

```
rtms_status_code rtms_message_queue_ident(  
    rtms_name  name,  
    uint32_t   node,  
    rtms_id    *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - queue identified successfully

RTEMS_INVALID_ADDRESS - id is NULL

RTEMS_INVALID_NAME - queue name not found

RTEMS_INVALID_NODE - invalid node id

DESCRIPTION:

This directive obtains the queue id associated with the queue name specified in name. If the queue name is not unique, then the queue id will match one of the queues with that name. However, this queue id is not guaranteed to correspond to the desired queue. The queue id is used with other message related directives to access the message queue.

NOTES:

This directive will not cause the running task to be preempted.

If node is RTEMS_SEARCH_ALL_NODES, all nodes are searched with the local node being searched first. All other nodes are searched with the lowest numbered node searched first.

If node is a valid node number which does not represent the local node, then only the message queues exported by the designated node are searched.

This directive does not generate activity on remote nodes. It accesses only the local copy of the global object table.

10.4.3 MESSAGE_QUEUE_DELETE - Delete a queue

CALLING SEQUENCE:

```
rtcms_status_code rtcms_message_queue_delete(  
    rtcms_id id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - queue deleted successfully

RTEMS_INVALID_ID - invalid queue id

RTEMS_ILLEGAL_ON_REMOTE_OBJECT - cannot delete remote queue

DESCRIPTION:

This directive deletes the message queue specified by id. As a result of this directive, all tasks blocked waiting to receive a message from this queue will be readied and returned a status code which indicates that the message queue was deleted. If no tasks are waiting, but the queue contains messages, then RTEMS returns these message buffers back to the system message buffer pool. The QCB for this queue as well as the memory for the message buffers is reclaimed by RTEMS.

NOTES:

The calling task will be preempted if its preemption mode is enabled and one or more local tasks with a higher priority than the calling task are waiting on the deleted queue. The calling task will NOT be preempted if the tasks that are waiting are remote tasks.

The calling task does not have to be the task that created the queue, although the task and queue must reside on the same node.

When the queue is deleted, any messages in the queue are returned to the free message buffer pool. Any information stored in those messages is lost.

When a global message queue is deleted, the message queue id must be transmitted to every node in the system for deletion from the local copy of the global object table.

Proxies, used to represent remote tasks, are reclaimed when the message queue is deleted.

10.4.4 MESSAGE_QUEUE_SEND - Put message at rear of a queue

CALLING SEQUENCE:

```
rtems_status_code rtems_message_queue_send(
    rtems_id    id,
    const void *buffer,
    size_t      size
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - message sent successfully

RTEMS_INVALID_ID - invalid queue id

RTEMS_INVALID_SIZE - invalid message size

RTEMS_INVALID_ADDRESS - buffer is NULL

RTEMS_UNSATISFIED - out of message buffers

RTEMS_TOO_MANY - queue's limit has been reached

DESCRIPTION:

This directive sends the message buffer of size bytes in length to the queue specified by id. If a task is waiting at the queue, then the message is copied to the waiting task's buffer and the task is unblocked. If no tasks are waiting at the queue, then the message is copied to a message buffer which is obtained from this message queue's message buffer pool. The message buffer is then placed at the rear of the queue.

NOTES:

The calling task will be preempted if it has preemption enabled and a higher priority task is unblocked as the result of this directive.

Sending a message to a global message queue which does not reside on the local node will generate a request to the remote node to post the message on the specified message queue.

If the task to be unblocked resides on a different node from the message queue, then the message is forwarded to the appropriate node, the waiting task is unblocked, and the proxy used to represent the task is reclaimed.

10.4.5 MESSAGE_QUEUE_URGENT - Put message at front of a queue

CALLING SEQUENCE:

```
rtems_status_code rtems_message_queue_urgent(  
    rtems_id    id,  
    const void *buffer,  
    size_t      size  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - message sent successfully
RTEMS_INVALID_ID - invalid queue id
RTEMS_INVALID_SIZE - invalid message size
RTEMS_INVALID_ADDRESS - buffer is NULL
RTEMS_UNSATISFIED - out of message buffers
RTEMS_TOO_MANY - queue's limit has been reached

DESCRIPTION:

This directive sends the message buffer of size bytes in length to the queue specified by id. If a task is waiting on the queue, then the message is copied to the task's buffer and the task is unblocked. If no tasks are waiting on the queue, then the message is copied to a message buffer which is obtained from this message queue's message buffer pool. The message buffer is then placed at the front of the queue.

NOTES:

The calling task will be preempted if it has preemption enabled and a higher priority task is unblocked as the result of this directive.

Sending a message to a global message queue which does not reside on the local node will generate a request telling the remote node to post the message on the specified message queue.

If the task to be unblocked resides on a different node from the message queue, then the message is forwarded to the appropriate node, the waiting task is unblocked, and the proxy used to represent the task is reclaimed.

10.4.6 MESSAGE_QUEUE_BROADCAST - Broadcast N messages to a queue

CALLING SEQUENCE:

```
rtems_status_code rtems_message_queue_broadcast(  
    rtems_id    id,  
    const void *buffer,  
    size_t      size,  
    uint32_t    *count  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - message broadcasted successfully

RTEMS_INVALID_ID - invalid queue id

RTEMS_INVALID_ADDRESS - buffer is NULL

RTEMS_INVALID_ADDRESS - count is NULL

RTEMS_INVALID_SIZE - invalid message size

DESCRIPTION:

This directive causes all tasks that are waiting at the queue specified by id to be unblocked and sent the message contained in buffer. Before a task is unblocked, the message buffer of size bytes in length is copied to that task's message buffer. The number of tasks that were unblocked is returned in count.

NOTES:

The calling task will be preempted if it has preemption enabled and a higher priority task is unblocked as the result of this directive.

The execution time of this directive is directly related to the number of tasks waiting on the message queue, although it is more efficient than the equivalent number of invocations of `rtems_message_queue_send`.

Broadcasting a message to a global message queue which does not reside on the local node will generate a request telling the remote node to broadcast the message to the specified message queue.

When a task is unblocked which resides on a different node from the message queue, a copy of the message is forwarded to the appropriate node, the waiting task is unblocked, and the proxy used to represent the task is reclaimed.

10.4.7 MESSAGE_QUEUE_RECEIVE - Receive message from a queue

CALLING SEQUENCE:

```

rtems_status_code rtems_message_queue_receive(
    rtems_id      id,
    void          *buffer,
    size_t        *size,
    rtems_option   option_set,
    rtems_interval timeout
);

```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - message received successfully

RTEMS_INVALID_ID - invalid queue id

RTEMS_INVALID_ADDRESS - buffer is NULL

RTEMS_INVALID_ADDRESS - size is NULL

RTEMS_UNSATISFIED - queue is empty

RTEMS_TIMEOUT - timed out waiting for message

RTEMS_OBJECT_WAS_DELETED - queue deleted while waiting

DESCRIPTION:

This directive receives a message from the message queue specified in `id`. The `RTEMS_WAIT` and `RTEMS_NO_WAIT` options of the options parameter allow the calling task to specify whether to wait for a message to become available or return immediately. For either option, if there is at least one message in the queue, then it is copied to `buffer`, `size` is set to return the length of the message in bytes, and this directive returns immediately with a successful return code. The buffer has to be big enough to receive a message of the maximum length with respect to this message queue.

If the calling task chooses to return immediately and the queue is empty, then a status code indicating this condition is returned. If the calling task chooses to wait at the message queue and the queue is empty, then the calling task is placed on the message wait queue and blocked. If the queue was created with the `RTEMS_PRIORITY` option specified, then the calling task is inserted into the wait queue according to its priority. But, if the queue was created with the `RTEMS_FIFO` option specified, then the calling task is placed at the rear of the wait queue.

A task choosing to wait at the queue can optionally specify a timeout value in the `timeout` parameter. The timeout parameter specifies the maximum interval to wait before the calling task desires to be unblocked. If it is set to `RTEMS_NO_TIMEOUT`, then the calling task will wait forever.

NOTES:

The following message receive option constants are defined by RTEMS:

- `RTEMS_WAIT` - task will wait for a message (default)
- `RTEMS_NO_WAIT` - task should not wait

Receiving a message from a global message queue which does not reside on the local node will generate a request to the remote node to obtain a message from the specified message queue. If no message is available and `RTEMS_WAIT` was specified, then the task must be blocked until a message is posted. A proxy is allocated on the remote node to represent the task until the message is posted.

A clock tick is required to support the timeout functionality of this directive.

10.4.8 MESSAGE_QUEUE_GET_NUMBER_PENDING - Get number of messages pending on a queue

CALLING SEQUENCE:

```
rtems_status_code rtems_message_queue_get_number_pending(  
    rtems_id id,  
    uint32_t *count  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - number of messages pending returned successfully

RTEMS_INVALID_ADDRESS - count is NULL

RTEMS_INVALID_ID - invalid queue id

DESCRIPTION:

This directive returns the number of messages pending on this message queue in count. If no messages are present on the queue, count is set to zero.

NOTES:

Getting the number of pending messages on a global message queue which does not reside on the local node will generate a request to the remote node to actually obtain the pending message count for the specified message queue.

10.4.9 MESSAGE_QUEUE_FLUSH - Flush all messages on a queue

CALLING SEQUENCE:

```
rtems_status_code rtems_message_queue_flush(  
    rtems_id id,  
    uint32_t *count  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - message queue flushed successfully

RTEMS_INVALID_ADDRESS - count is NULL

RTEMS_INVALID_ID - invalid queue id

DESCRIPTION:

This directive removes all pending messages from the specified queue id. The number of messages removed is returned in count. If no messages are present on the queue, count is set to zero.

NOTES:

Flushing all messages on a global message queue which does not reside on the local node will generate a request to the remote node to actually flush the specified message queue.

11 Event Manager

11.1 Introduction

The event manager provides a high performance method of intertask communication and synchronization. The directives provided by the event manager are:

- `rtems_event_send` - Send event set to a task
- `rtems_event_receive` - Receive event condition

11.2 Background

11.2.1 Event Sets

An event flag is used by a task (or ISR) to inform another task of the occurrence of a significant situation. Thirty-two event flags are associated with each task. A collection of one or more event flags is referred to as an event set. The data type `rtems_event_set` is used to manage event sets.

The application developer should remember the following key characteristics of event operations when utilizing the event manager:

- Events provide a simple synchronization facility.
- Events are aimed at tasks.
- Tasks can wait on more than one event simultaneously.
- Events are independent of one another.
- Events do not hold or transport data.
- Events are not queued. In other words, if an event is sent more than once to a task before being received, the second and subsequent send operations to that same task have no effect.

An event set is posted when it is directed (or sent) to a task. A pending event is an event that has been posted but not received. An event condition is used to specify the event set which the task desires to receive and the algorithm which will be used to determine when the request is satisfied. An event condition is satisfied based upon one of two algorithms which are selected by the user. The `RTEMS_EVENT_ANY` algorithm states that an event condition is satisfied when at least a single requested event is posted. The `RTEMS_EVENT_ALL` algorithm states that an event condition is satisfied when every requested event is posted.

11.2.2 Building an Event Set or Condition

An event set or condition is built by a bitwise OR of the desired events. The set of valid events is `RTEMS_EVENT_0` through `RTEMS_EVENT_31`. If an event is not explicitly specified in the set or condition, then it is not present. Events are specifically designed to be mutually exclusive, therefore bitwise OR and addition operations are equivalent as long as each event appears exactly once in the event set list.

For example, when sending the event set consisting of `RTEMS_EVENT_6`, `RTEMS_EVENT_15`, and `RTEMS_EVENT_31`, the event parameter to the `rtems_event_send` directive should be `RTEMS_EVENT_6 | RTEMS_EVENT_15 | RTEMS_EVENT_31`.

11.2.3 Building an `EVENT_RECEIVE` Option Set

In general, an option is built by a bitwise OR of the desired option components. The set of valid options for the `rtems_event_receive` directive are listed in the following table:

- `RTEMS_WAIT` - task will wait for event (default)
- `RTEMS_NO_WAIT` - task should not wait
- `RTEMS_EVENT_ALL` - return after all events (default)
- `RTEMS_EVENT_ANY` - return after any events

Option values are specifically designed to be mutually exclusive, therefore bitwise OR and addition operations are equivalent as long as each option appears exactly once in the component list. An option listed as a default is not required to appear in the option list, although it is a good programming practice to specify default options. If all defaults are desired, the option `RTEMS_DEFAULT_OPTIONS` should be specified on this call.

This example demonstrates the option parameter needed to poll for all events in a particular event condition to arrive. The option parameter passed to the `rtems_event_receive` directive should be either `RTEMS_EVENT_ALL | RTEMS_NO_WAIT` or `RTEMS_NO_WAIT`. The option parameter can be set to `RTEMS_NO_WAIT` because `RTEMS_EVENT_ALL` is the default condition for `rtems_event_receive`.

11.3 Operations

11.3.1 Sending an Event Set

The `rtems_event_send` directive allows a task (or an ISR) to direct an event set to a target task. Based upon the state of the target task, one of the following situations applies:

- Target Task is Blocked Waiting for Events
 - If the waiting task's input event condition is satisfied, then the task is made ready for execution.
 - If the waiting task's input event condition is not satisfied, then the event set is posted but left pending and the task remains blocked.
- Target Task is Not Waiting for Events
 - The event set is posted and left pending.

11.3.2 Receiving an Event Set

The `rtems_event_receive` directive is used by tasks to accept a specific input event condition. The task also specifies whether the request is satisfied when all requested events are available or any single requested event is available. If the requested event condition is satisfied by pending events, then a successful return code and the satisfying event set are returned immediately. If the condition is not satisfied, then one of the following situations applies:

- By default, the calling task will wait forever for the event condition to be satisfied.
- Specifying the `RTEMS_NO_WAIT` option forces an immediate return with an error status code.

- Specifying a timeout limits the period the task will wait before returning with an error status code.

11.3.3 Determining the Pending Event Set

A task can determine the pending event set by calling the `rtems_event_receive` directive with a value of `RTEMS_PENDING_EVENTS` for the input event condition. The pending events are returned to the calling task but the event set is left unaltered.

11.3.4 Receiving all Pending Events

A task can receive all of the currently pending events by calling the `rtems_event_receive` directive with a value of `RTEMS_ALL_EVENTS` for the input event condition and `RTEMS_NO_WAIT | RTEMS_EVENT_ANY` for the option set. The pending events are returned to the calling task and the event set is cleared. If no events are pending then the `RTEMS_UNSATISFIED` status code will be returned.

11.4 Directives

This section details the event manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

11.4.1 EVENT_SEND - Send event set to a task

CALLING SEQUENCE:

```
rtems_status_code rtems_event_send (  
    rtems_id      id,  
    rtems_event_set event_in  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - event set sent successfully

RTEMS_INVALID_ID - invalid task id

DESCRIPTION:

This directive sends an event set, `event_in`, to the task specified by `id`. If a blocked task's input event condition is satisfied by this directive, then it will be made ready. If its input event condition is not satisfied, then the events satisfied are updated and the events not satisfied are left pending. If the task specified by `id` is not blocked waiting for events, then the events sent are left pending.

NOTES:

Specifying `RTEMS_SELF` for `id` results in the event set being sent to the calling task.

Identical events sent to a task are not queued. In other words, the second, and subsequent, posting of an event to a task before it can perform an `rtems_event_receive` has no effect.

The calling task will be preempted if it has preemption enabled and a higher priority task is unblocked as the result of this directive.

Sending an event set to a global task which does not reside on the local node will generate a request telling the remote node to send the event set to the appropriate task.

11.4.2 EVENT_RECEIVE - Receive event condition

CALLING SEQUENCE:

```

rtems_status_code rtems_event_receive (
    rtems_event_set  event_in,
    rtems_option      option_set,
    rtems_interval    ticks,
    rtems_event_set  *event_out
);

```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - event received successfully
RTEMS_UNSATISFIED - input event not satisfied (**RTEMS_NO_WAIT**)
RTEMS_INVALID_ADDRESS - `event_out` is NULL
RTEMS_TIMEOUT - timed out waiting for event

DESCRIPTION:

This directive attempts to receive the event condition specified in `event_in`. If `event_in` is set to **RTEMS_PENDING_EVENTS**, then the current pending events are returned in `event_out` and left pending. The **RTEMS_WAIT** and **RTEMS_NO_WAIT** options in the `option_set` parameter are used to specify whether or not the task is willing to wait for the event condition to be satisfied. **RTEMS_EVENT_ANY** and **RTEMS_EVENT_ALL** are used in the `option_set` parameter are used to specify whether a single event or the complete event set is necessary to satisfy the event condition. The `event_out` parameter is returned to the calling task with the value that corresponds to the events in `event_in` that were satisfied.

If pending events satisfy the event condition, then `event_out` is set to the satisfied events and the pending events in the event condition are cleared. If the event condition is not satisfied and **RTEMS_NO_WAIT** is specified, then `event_out` is set to the currently satisfied events. If the calling task chooses to wait, then it will block waiting for the event condition.

If the calling task must wait for the event condition to be satisfied, then the `timeout` parameter is used to specify the maximum interval to wait. If it is set to **RTEMS_NO_TIMEOUT**, then the calling task will wait forever.

NOTES:

This directive only affects the events specified in `event_in`. Any pending events that do not correspond to any of the events specified in `event_in` will be left pending.

The following event receive option constants are defined by RTEMS:

- **RTEMS_WAIT** task will wait for event (default)
- **RTEMS_NO_WAIT** task should not wait
- **RTEMS_EVENT_ALL** return after all events (default)
- **RTEMS_EVENT_ANY** return after any events

A clock tick is required to support the functionality of this directive.

12 Signal Manager

12.1 Introduction

The signal manager provides the capabilities required for asynchronous communication. The directives provided by the signal manager are:

- `rtems_signal_catch` - Establish an ASR
- `rtems_signal_send` - Send signal set to a task

12.2 Background

12.2.1 Signal Manager Definitions

The signal manager allows a task to optionally define an asynchronous signal routine (ASR). An ASR is to a task what an ISR is to an application's set of tasks. When the processor is interrupted, the execution of an application is also interrupted and an ISR is given control. Similarly, when a signal is sent to a task, that task's execution path will be "interrupted" by the ASR. Sending a signal to a task has no effect on the receiving task's current execution state.

A signal flag is used by a task (or ISR) to inform another task of the occurrence of a significant situation. Thirty-two signal flags are associated with each task. A collection of one or more signals is referred to as a signal set. The data type `rtems_signal_set` is used to manipulate signal sets.

A signal set is posted when it is directed (or sent) to a task. A pending signal is a signal that has been sent to a task with a valid ASR, but has not been processed by that task's ASR.

12.2.2 A Comparison of ASRs and ISRs

The format of an ASR is similar to that of an ISR with the following exceptions:

- ISRs are scheduled by the processor hardware. ASRs are scheduled by RTEMS.
- ISRs do not execute in the context of a task and may invoke only a subset of directives. ASRs execute in the context of a task and may execute any directive.
- When an ISR is invoked, it is passed the vector number as its argument. When an ASR is invoked, it is passed the signal set as its argument.
- An ASR has a task mode which can be different from that of the task. An ISR does not execute as a task and, as a result, does not have a task mode.

12.2.3 Building a Signal Set

A signal set is built by a bitwise OR of the desired signals. The set of valid signals is `RTEMS_SIGNAL_0` through `RTEMS_SIGNAL_31`. If a signal is not explicitly specified in the signal set, then it is not present. Signal values are specifically designed to be mutually exclusive, therefore bitwise OR and addition operations are equivalent as long as each signal appears exactly once in the component list.

This example demonstrates the signal parameter used when sending the signal set consisting of `RTEMS_SIGNAL_6`, `RTEMS_SIGNAL_15`, and `RTEMS_SIGNAL_31`. The signal parameter provided to the `rtems_signal_send` directive should be `RTEMS_SIGNAL_6 | RTEMS_SIGNAL_15 | RTEMS_SIGNAL_31`.

12.2.4 Building an ASR Mode

In general, an ASR's mode is built by a bitwise OR of the desired mode components. The set of valid mode components is the same as those allowed with the `task_create` and `task_mode` directives. A complete list of mode options is provided in the following table:

- `RTEMS_PREEMPT` is masked by `RTEMS_PREEMPT_MASK` and enables preemption
- `RTEMS_NO_PREEMPT` is masked by `RTEMS_PREEMPT_MASK` and disables preemption
- `RTEMS_NO_TIMESLICE` is masked by `RTEMS_TIMESLICE_MASK` and disables timeslicing
- `RTEMS_TIMESLICE` is masked by `RTEMS_TIMESLICE_MASK` and enables timeslicing
- `RTEMS_ASR` is masked by `RTEMS_ASR_MASK` and enables ASR processing
- `RTEMS_NO_ASR` is masked by `RTEMS_ASR_MASK` and disables ASR processing
- `RTEMS_INTERRUPT_LEVEL(0)` is masked by `RTEMS_INTERRUPT_MASK` and enables all interrupts
- `RTEMS_INTERRUPT_LEVEL(n)` is masked by `RTEMS_INTERRUPT_MASK` and sets interrupts level `n`

Mode values are specifically designed to be mutually exclusive, therefore bitwise OR and addition operations are equivalent as long as each mode appears exactly once in the component list. A mode component listed as a default is not required to appear in the mode list, although it is a good programming practice to specify default components. If all defaults are desired, the mode `DEFAULT_MODES` should be specified on this call.

This example demonstrates the mode parameter used with the `rtems_signal_catch` to establish an ASR which executes at interrupt level three and is non-preemptible. The mode should be set to `RTEMS_INTERRUPT_LEVEL(3) | RTEMS_NO_PREEMPT` to indicate the desired processor mode and interrupt level.

12.3 Operations

12.3.1 Establishing an ASR

The `rtems_signal_catch` directive establishes an ASR for the calling task. The address of the ASR and its execution mode are specified to this directive. The ASR's mode is distinct from the task's mode. For example, the task may allow preemption, while that task's ASR may have preemption disabled. Until a task calls `rtems_signal_catch` the first time, its ASR is invalid, and no signal sets can be sent to the task.

A task may invalidate its ASR and discard all pending signals by calling `rtems_signal_catch` with a value of `NULL` for the ASR's address. When a task's ASR is invalid, new signal sets sent to this task are discarded.

A task may disable ASR processing (`RTEMS_NO_ASR`) via the `task_mode` directive. When a task's ASR is disabled, the signals sent to it are left pending to be processed later when the ASR is enabled.

Any directive that can be called from a task can also be called from an ASR. A task is only allowed one active ASR. Thus, each call to `rtems_signal_catch` replaces the previous one.

Normally, signal processing is disabled for the ASR's execution mode, but if signal processing is enabled for the ASR, the ASR must be reentrant.

12.3.2 Sending a Signal Set

The `rtems_signal_send` directive allows both tasks and ISRs to send signals to a target task. The target task and a set of signals are specified to the `rtems_signal_send` directive. The sending of a signal to a task has no effect on the execution state of that task. If the task is not the currently running task, then the signals are left pending and processed by the task's ASR the next time the task is dispatched to run. The ASR is executed immediately before the task is dispatched. If the currently running task sends a signal to itself or is sent a signal from an ISR, its ASR is immediately dispatched to run provided signal processing is enabled.

If an ASR with signals enabled is preempted by another task or an ISR and a new signal set is sent, then a new copy of the ASR will be invoked, nesting the preempted ASR. Upon completion of processing the new signal set, control will return to the preempted ASR. In this situation, the ASR must be reentrant.

Like events, identical signals sent to a task are not queued. In other words, sending the same signal multiple times to a task (without any intermediate signal processing occurring for the task), has the same result as sending that signal to that task once.

12.3.3 Processing an ASR

Asynchronous signals were designed to provide the capability to generate software interrupts. The processing of software interrupts parallels that of hardware interrupts. As a result, the differences between the formats of ASRs and ISRs is limited to the meaning of the single argument passed to an ASR. The ASR should have the following calling sequence and adhere to C calling conventions:

```
rtems_asr user_routine(  
    rtems_signal_set signals  
);
```

When the ASR returns to RTEMS the mode and execution path of the interrupted task (or ASR) is restored to the context prior to entering the ASR.

12.4 Directives

This section details the signal manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

12.4.1 SIGNAL_CATCH - Establish an ASR

CALLING SEQUENCE:

```
rtems_status_code rtems_signal_catch(  
    rtems_asr_entry asr_handler,  
    rtems_mode mode  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - always successful

DESCRIPTION:

This directive establishes an asynchronous signal routine (ASR) for the calling task. The `asr_handler` parameter specifies the entry point of the ASR. If `asr_handler` is `NULL`, the ASR for the calling task is invalidated and all pending signals are cleared. Any signals sent to a task with an invalid ASR are discarded. The mode parameter specifies the execution mode for the ASR. This execution mode supersedes the task's execution mode while the ASR is executing.

NOTES:

This directive will not cause the calling task to be preempted.

The following task mode constants are defined by RTEMS:

- `RTEMS_PREEMPT` is masked by `RTEMS_PREEMPT_MASK` and enables preemption
- `RTEMS_NO_PREEMPT` is masked by `RTEMS_PREEMPT_MASK` and disables preemption
- `RTEMS_NO_TIMESLICE` is masked by `RTEMS_TIMESLICE_MASK` and disables timeslicing
- `RTEMS_TIMESLICE` is masked by `RTEMS_TIMESLICE_MASK` and enables timeslicing
- `RTEMS_ASR` is masked by `RTEMS_ASR_MASK` and enables ASR processing
- `RTEMS_NO_ASR` is masked by `RTEMS_ASR_MASK` and disables ASR processing
- `RTEMS_INTERRUPT_LEVEL(0)` is masked by `RTEMS_INTERRUPT_MASK` and enables all interrupts
- `RTEMS_INTERRUPT_LEVEL(n)` is masked by `RTEMS_INTERRUPT_MASK` and sets interrupts level `n`

12.4.2 SIGNAL_SEND - Send signal set to a task

CALLING SEQUENCE:

```
rtems_status_code rtems_signal_send(  
    rtems_id      id,  
    rtems_signal_set signal_set  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - signal sent successfully

RTEMS_INVALID_ID - task id invalid

RTEMS_INVALID_NUMBER - empty signal set

RTEMS_NOT_DEFINED - ASR invalid

DESCRIPTION:

This directive sends a signal set to the task specified in `id`. The `signal_set` parameter contains the signal set to be sent to the task.

If a caller sends a signal set to a task with an invalid ASR, then an error code is returned to the caller. If a caller sends a signal set to a task whose ASR is valid but disabled, then the signal set will be caught and left pending for the ASR to process when it is enabled. If a caller sends a signal set to a task with an ASR that is both valid and enabled, then the signal set is caught and the ASR will execute the next time the task is dispatched to run.

NOTES:

Sending a signal set to a task has no effect on that task's state. If a signal set is sent to a blocked task, then the task will remain blocked and the signals will be processed when the task becomes the running task.

Sending a signal set to a global task which does not reside on the local node will generate a request telling the remote node to send the signal set to the specified task.

13 Partition Manager

13.1 Introduction

The partition manager provides facilities to dynamically allocate memory in fixed-size units. The directives provided by the partition manager are:

- `rtems_partition_create` - Create a partition
- `rtems_partition_ident` - Get ID of a partition
- `rtems_partition_delete` - Delete a partition
- `rtems_partition_get_buffer` - Get buffer from a partition
- `rtems_partition_return_buffer` - Return buffer to a partition

13.2 Background

13.2.1 Partition Manager Definitions

A partition is a physically contiguous memory area divided into fixed-size buffers that can be dynamically allocated and deallocated.

Partitions are managed and maintained as a list of buffers. Buffers are obtained from the front of the partition's free buffer chain and returned to the rear of the same chain. When a buffer is on the free buffer chain, RTEMS uses two pointers of memory from each buffer as the free buffer chain. When a buffer is allocated, the entire buffer is available for application use. Therefore, modifying memory that is outside of an allocated buffer could destroy the free buffer chain or the contents of an adjacent allocated buffer.

13.2.2 Building a Partition Attribute Set

In general, an attribute set is built by a bitwise OR of the desired attribute components. The set of valid partition attributes is provided in the following table:

- `RTEMS_LOCAL` - local task (default)
- `RTEMS_GLOBAL` - global task

Attribute values are specifically designed to be mutually exclusive, therefore bitwise OR and addition operations are equivalent as long as each attribute appears exactly once in the component list. An attribute listed as a default is not required to appear in the attribute list, although it is a good programming practice to specify default attributes. If all defaults are desired, the attribute `RTEMS_DEFAULT_ATTRIBUTES` should be specified on this call. The `attribute_set` parameter should be `RTEMS_GLOBAL` to indicate that the partition is to be known globally.

13.3 Operations

13.3.1 Creating a Partition

The `rtems_partition_create` directive creates a partition with a user-specified name. The partition's name, starting address, length and buffer size are all specified to the `rtems_partition_create` directive. RTEMS allocates a Partition Control Block (PCB)

from the PTCB free list. This data structure is used by RTEMS to manage the newly created partition. The number of buffers in the partition is calculated based upon the specified partition length and buffer size. If successful, the unique partition ID is returned to the calling task.

13.3.2 Obtaining Partition IDs

When a partition is created, RTEMS generates a unique partition ID and assigned it to the created partition until it is deleted. The partition ID may be obtained by either of two methods. First, as the result of an invocation of the `rtems_partition_create` directive, the partition ID is stored in a user provided location. Second, the partition ID may be obtained later using the `rtems_partition_ident` directive. The partition ID is used by other partition manager directives to access this partition.

13.3.3 Acquiring a Buffer

A buffer can be obtained by calling the `rtems_partition_get_buffer` directive. If a buffer is available, then it is returned immediately with a successful return code. Otherwise, an unsuccessful return code is returned immediately to the caller. Tasks cannot block to wait for a buffer to become available.

13.3.4 Releasing a Buffer

Buffers are returned to a partition's free buffer chain with the `rtems_partition_return_buffer` directive. This directive returns an error status code if the returned buffer was not previously allocated from this partition.

13.3.5 Deleting a Partition

The `rtems_partition_delete` directive allows a partition to be removed and returned to RTEMS. When a partition is deleted, the PTCB for that partition is returned to the PTCB free list. A partition with buffers still allocated cannot be deleted. Any task attempting to do so will be returned an error status code.

13.4 Directives

This section details the partition manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

13.4.1 PARTITION_CREATE - Create a partition

CALLING SEQUENCE:

```

    rtems_status_code rtems_partition_create(
        rtems_name      name,
        void             *starting_address,
        uint32_t         length,
        uint32_t         buffer_size,
        rtems_attribute  attribute_set,
        rtems_id         *id
    );

```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - partition created successfully
 RTEMS_INVALID_NAME - invalid partition name
 RTEMS_TOO_MANY - too many partitions created
 RTEMS_INVALID_ADDRESS - address not on four byte boundary
 RTEMS_INVALID_ADDRESS - `starting_address` is NULL
 RTEMS_INVALID_ADDRESS - `id` is NULL
 RTEMS_INVALID_SIZE - length or buffer size is 0
 RTEMS_INVALID_SIZE - length is less than the buffer size
 RTEMS_INVALID_SIZE - buffer size not a multiple of 4
 RTEMS_MP_NOT_CONFIGURED - multiprocessing not configured
 RTEMS_TOO_MANY - too many global objects

DESCRIPTION:

This directive creates a partition of fixed size buffers from a physically contiguous memory space which starts at `starting_address` and is `length` bytes in size. Each allocated buffer is to be of `buffer_size` in bytes. The assigned partition id is returned in `id`. This partition id is used to access the partition with other partition related directives. For control and maintenance of the partition, RTEMS allocates a PTCB from the local PTCB free pool and initializes it.

NOTES:

This directive will not cause the calling task to be preempted.

The `starting_address` must be properly aligned for the target architecture.

The `buffer_size` parameter must be a multiple of the CPU alignment factor. Additionally, `buffer_size` must be large enough to hold two pointers on the target architecture. This is required for RTEMS to manage the buffers when they are free.

Memory from the partition is not used by RTEMS to store the Partition Control Block.

The following partition attribute constants are defined by RTEMS:

- RTEMS_LOCAL - local task (default)
- RTEMS_GLOBAL - global task

The PTCB for a global partition is allocated on the local node. The memory space used for the partition must reside in shared memory. Partitions should not be made global unless remote tasks must interact with the partition. This is to avoid the overhead incurred by the creation of a global partition. When a global partition is created, the partition's name and id must be transmitted to every node in the system for insertion in the local copy of the global object table.

The total number of global objects, including partitions, is limited by the `maximum_global_objects` field in the Configuration Table.

13.4.2 PARTITION_IDENT - Get ID of a partition

CALLING SEQUENCE:

```
rtcms_status_code rtcms_partition_ident(  
    rtcms_name  name,  
    uint32_t    node,  
    rtcms_id    *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - partition identified successfully

RTEMS_INVALID_ADDRESS - id is NULL

RTEMS_INVALID_NAME - partition name not found

RTEMS_INVALID_NODE - invalid node id

DESCRIPTION:

This directive obtains the partition id associated with the partition name. If the partition name is not unique, then the partition id will match one of the partitions with that name. However, this partition id is not guaranteed to correspond to the desired partition. The partition id is used with other partition related directives to access the partition.

NOTES:

This directive will not cause the running task to be preempted.

If node is RTEMS_SEARCH_ALL_NODES, all nodes are searched with the local node being searched first. All other nodes are searched with the lowest numbered node searched first.

If node is a valid node number which does not represent the local node, then only the partitions exported by the designated node are searched.

This directive does not generate activity on remote nodes. It accesses only the local copy of the global object table.

13.4.3 PARTITION_DELETE - Delete a partition

CALLING SEQUENCE:

```
rtcms_status_code rtcms_partition_delete(  
    rtcms_id id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - partition deleted successfully

RTEMS_INVALID_ID - invalid partition id

RTEMS_RESOURCE_IN_USE - buffers still in use

RTEMS_ILLEGAL_ON_REMOTE_OBJECT - cannot delete remote partition

DESCRIPTION:

This directive deletes the partition specified by id. The partition cannot be deleted if any of its buffers are still allocated. The PTCB for the deleted partition is reclaimed by RTEMS.

NOTES:

This directive will not cause the calling task to be preempted.

The calling task does not have to be the task that created the partition. Any local task that knows the partition id can delete the partition.

When a global partition is deleted, the partition id must be transmitted to every node in the system for deletion from the local copy of the global object table.

The partition must reside on the local node, even if the partition was created with the RTEMS_GLOBAL option.

13.4.4 PARTITION_GET_BUFFER - Get buffer from a partition

CALLING SEQUENCE:

```
rtems_status_code rtems_partition_get_buffer(  
    rtems_id    id,  
    void        **buffer  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - buffer obtained successfully

RTEMS_INVALID_ADDRESS - buffer is NULL

RTEMS_INVALID_ID - invalid partition id

RTEMS_UNSATISFIED - all buffers are allocated

DESCRIPTION:

This directive allows a buffer to be obtained from the partition specified in id. The address of the allocated buffer is returned in buffer.

NOTES:

This directive will not cause the running task to be preempted.

All buffers begin on a four byte boundary.

A task cannot wait on a buffer to become available.

Getting a buffer from a global partition which does not reside on the local node will generate a request telling the remote node to allocate a buffer from the specified partition.

13.4.5 PARTITION_RETURN_BUFFER - Return buffer to a partition

CALLING SEQUENCE:

```
rtems_status_code rtems_partition_return_buffer(  
    rtems_id id,  
    void      *buffer  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - buffer returned successfully

RTEMS_INVALID_ADDRESS - `buffer` is NULL

RTEMS_INVALID_ID - invalid partition id

RTEMS_INVALID_ADDRESS - buffer address not in partition

DESCRIPTION:

This directive returns the buffer specified by `buffer` to the partition specified by `id`.

NOTES:

This directive will not cause the running task to be preempted.

Returning a buffer to a global partition which does not reside on the local node will generate a request telling the remote node to return the buffer to the specified partition.

Returning a buffer multiple times is an error. It will corrupt the internal state of the partition.

14 Region Manager

14.1 Introduction

The region manager provides facilities to dynamically allocate memory in variable sized units. The directives provided by the region manager are:

- `rtems_region_create` - Create a region
- `rtems_region_ident` - Get ID of a region
- `rtems_region_delete` - Delete a region
- `rtems_region_extend` - Add memory to a region
- `rtems_region_get_segment` - Get segment from a region
- `rtems_region_return_segment` - Return segment to a region
- `rtems_region_get_segment_size` - Obtain size of a segment
- `rtems_region_resize_segment` - Change size of a segment

14.2 Background

14.2.1 Region Manager Definitions

A region makes up a physically contiguous memory space with user-defined boundaries from which variable-sized segments are dynamically allocated and deallocated. A segment is a variable size section of memory which is allocated in multiples of a user-defined page size. This page size is required to be a multiple of four greater than or equal to four. For example, if a request for a 350-byte segment is made in a region with 256-byte pages, then a 512-byte segment is allocated.

Regions are organized as doubly linked chains of variable sized memory blocks. Memory requests are allocated using a first-fit algorithm. If available, the requester receives the number of bytes requested (rounded up to the next page size). RTEMS requires some overhead from the region's memory for each segment that is allocated. Therefore, an application should only modify the memory of a segment that has been obtained from the region. The application should NOT modify the memory outside of any obtained segments and within the region's boundaries while the region is currently active in the system.

Upon return to the region, the free block is coalesced with its neighbors (if free) on both sides to produce the largest possible unused block.

14.2.2 Building an Attribute Set

In general, an attribute set is built by a bitwise OR of the desired attribute components. The set of valid region attributes is provided in the following table:

- `RTEMS_FIFO` - tasks wait by FIFO (default)
- `RTEMS_PRIORITY` - tasks wait by priority

Attribute values are specifically designed to be mutually exclusive, therefore bitwise OR and addition operations are equivalent as long as each attribute appears exactly once in the component list. An attribute listed as a default is not required to appear in the attribute

list, although it is a good programming practice to specify default attributes. If all defaults are desired, the attribute `RTEMS_DEFAULT_ATTRIBUTES` should be specified on this call.

This example demonstrates the `attribute_set` parameter needed to create a region with the task priority waiting queue discipline. The `attribute_set` parameter to the `rtems_region_create` directive should be `RTEMS_PRIORITY`.

14.2.3 Building an Option Set

In general, an option is built by a bitwise OR of the desired option components. The set of valid options for the `rtems_region_get_segment` directive are listed in the following table:

- `RTEMS_WAIT` - task will wait for segment (default)
- `RTEMS_NO_WAIT` - task should not wait

Option values are specifically designed to be mutually exclusive, therefore bitwise OR and addition operations are equivalent as long as each option appears exactly once in the component list. An option listed as a default is not required to appear in the option list, although it is a good programming practice to specify default options. If all defaults are desired, the option `RTEMS_DEFAULT_OPTIONS` should be specified on this call.

This example demonstrates the option parameter needed to poll for a segment. The option parameter passed to the `rtems_region_get_segment` directive should be `RTEMS_NO_WAIT`.

14.3 Operations

14.3.1 Creating a Region

The `rtems_region_create` directive creates a region with the user-defined name. The user may select FIFO or task priority as the method for placing waiting tasks in the task wait queue. RTEMS allocates a Region Control Block (RNCB) from the RNCB free list to maintain the newly created region. RTEMS also generates a unique region ID which is returned to the calling task.

It is not possible to calculate the exact number of bytes available to the user since RTEMS requires overhead for each segment allocated. For example, a region with one segment that is the size of the entire region has more available bytes than a region with two segments that collectively are the size of the entire region. This is because the region with one segment requires only the overhead for one segment, while the other region requires the overhead for two segments.

Due to automatic coalescing, the number of segments in the region dynamically changes. Therefore, the total overhead required by RTEMS dynamically changes.

14.3.2 Obtaining Region IDs

When a region is created, RTEMS generates a unique region ID and assigns it to the created region until it is deleted. The region ID may be obtained by either of two methods. First, as the result of an invocation of the `rtems_region_create` directive, the region ID is stored in a user provided location. Second, the region ID may be obtained later using the `rtems_region_ident` directive. The region ID is used by other region manager directives to access this region.

14.3.3 Adding Memory to a Region

The `rtems_region_extend` directive may be used to add memory to an existing region. The caller specifies the size in bytes and starting address of the memory being added.

NOTE: Please see the release notes or RTEMS source code for information regarding restrictions on the location of the memory being added in relation to memory already in the region.

14.3.4 Acquiring a Segment

The `rtems_region_get_segment` directive attempts to acquire a segment from a specified region. If the region has enough available free memory, then a segment is returned successfully to the caller. When the segment cannot be allocated, one of the following situations applies:

- By default, the calling task will wait forever to acquire the segment.
- Specifying the `RTEMS_NO_WAIT` option forces an immediate return with an error status code.
- Specifying a timeout limits the interval the task will wait before returning with an error status code.

If the task waits for the segment, then it is placed in the region's task wait queue in either FIFO or task priority order. All tasks waiting on a region are returned an error when the message queue is deleted.

14.3.5 Releasing a Segment

When a segment is returned to a region by the `rtems_region_return_segment` directive, it is merged with its unallocated neighbors to form the largest possible segment. The first task on the wait queue is examined to determine if its segment request can now be satisfied. If so, it is given a segment and unblocked. This process is repeated until the first task's segment request cannot be satisfied.

14.3.6 Obtaining the Size of a Segment

The `rtems_region_get_segment_size` directive returns the size in bytes of the specified segment. The size returned includes any "extra" memory included in the segment because of rounding up to a page size boundary.

14.3.7 Changing the Size of a Segment

The `rtems_region_resize_segment` directive is used to change the size in bytes of the specified segment. The size may be increased or decreased. When increasing the size of a segment, it is possible that the request cannot be satisfied. This directive provides functionality similar to the `realloc()` function in the Standard C Library.

14.3.8 Deleting a Region

A region can be removed from the system and returned to RTEMS with the `rtems_region_delete` directive. When a region is deleted, its control block is returned to the RNCB free list. A region with segments still allocated is not allowed to be deleted. Any task attempting to do so will be returned an error. As a result of this directive, all tasks blocked waiting to

obtain a segment from the region will be readied and returned a status code which indicates that the region was deleted.

14.4 Directives

This section details the region manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

14.4.1 REGION_CREATE - Create a region

CALLING SEQUENCE:

```

rtems_status_code rtems_region_create(
    rtems_name      name,
    void            *starting_address,
    intptr_t        length,
    uint32_t         page_size,
    rtems_attribute attribute_set,
    rtems_id        *id
);

```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - region created successfully
 RTEMS_INVALID_NAME - invalid region name
 RTEMS_INVALID_ADDRESS - id is NULL
 RTEMS_INVALID_ADDRESS - starting_address is NULL
 RTEMS_INVALID_ADDRESS - address not on four byte boundary
 RTEMS_TOO_MANY - too many regions created
 RTEMS_INVALID_SIZE - invalid page size

DESCRIPTION:

This directive creates a region from a physically contiguous memory space which starts at starting_address and is length bytes long. Segments allocated from the region will be a multiple of page_size bytes in length. The assigned region id is returned in id. This region id is used as an argument to other region related directives to access the region.

For control and maintenance of the region, RTEMS allocates and initializes an RNCB from the RNCB free pool. Thus memory from the region is not used to store the RNCB. However, some overhead within the region is required by RTEMS each time a segment is constructed in the region.

Specifying RTEMS_PRIORITY in attribute_set causes tasks waiting for a segment to be serviced according to task priority. Specifying RTEMS_FIFO in attribute_set or selecting RTEMS_DEFAULT_ATTRIBUTES will cause waiting tasks to be serviced in First In-First Out order.

The starting_address parameter must be aligned on a four byte boundary. The page_size parameter must be a multiple of four greater than or equal to eight.

NOTES:

This directive will not cause the calling task to be preempted.

The following region attribute constants are defined by RTEMS:

- RTEMS_FIFO - tasks wait by FIFO (default)
- RTEMS_PRIORITY - tasks wait by priority

14.4.2 REGION_IDENT - Get ID of a region

CALLING SEQUENCE:

```
rtems_status_code rtems_region_ident(  
    rtems_name  name,  
    rtems_id    *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - region identified successfully

RTEMS_INVALID_ADDRESS - id is NULL

RTEMS_INVALID_NAME - region name not found

DESCRIPTION:

This directive obtains the region id associated with the region name to be acquired. If the region name is not unique, then the region id will match one of the regions with that name. However, this region id is not guaranteed to correspond to the desired region. The region id is used to access this region in other region manager directives.

NOTES:

This directive will not cause the running task to be preempted.

14.4.3 REGION_DELETE - Delete a region

CALLING SEQUENCE:

```
    rtems_status_code rtems_region_delete(  
        rtems_id id  
    );
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - region deleted successfully

RTEMS_INVALID_ID - invalid region id

RTEMS_RESOURCE_IN_USE - segments still in use

DESCRIPTION:

This directive deletes the region specified by id. The region cannot be deleted if any of its segments are still allocated. The RNCB for the deleted region is reclaimed by RTEMS.

NOTES:

This directive will not cause the calling task to be preempted.

The calling task does not have to be the task that created the region. Any local task that knows the region id can delete the region.

14.4.4 REGION_EXTEND - Add memory to a region

CALLING SEQUENCE:

```
rtems_status_code rtems_region_extend(  
    rtems_id id,  
    void      *starting_address,  
    intptr_t  length  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - region extended successfully

RTEMS_INVALID_ADDRESS - `starting_address` is NULL

RTEMS_INVALID_ID - invalid region id

RTEMS_INVALID_ADDRESS - invalid address of area to add

DESCRIPTION:

This directive adds the memory which starts at `starting_address` for `length` bytes to the region specified by `id`.

NOTES:

This directive will not cause the calling task to be preempted.

The calling task does not have to be the task that created the region. Any local task that knows the region id can extend the region.

14.4.5 REGION_GET_SEGMENT - Get segment from a region

CALLING SEQUENCE:

```

rtems_status_code rtems_region_get_segment(
    rtems_id      id,
    intptr_t      size,
    rtems_option   option_set,
    rtems_interval timeout,
    void          **segment
);

```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - segment obtained successfully

RTEMS_INVALID_ADDRESS - `segment` is NULL

RTEMS_INVALID_ID - invalid region id

RTEMS_INVALID_SIZE - request is for zero bytes or exceeds the size of maximum segment which is possible for this region

RTEMS_UNSATISFIED - segment of requested size not available

RTEMS_TIMEOUT - timed out waiting for segment

RTEMS_OBJECT_WAS_DELETED - region deleted while waiting

DESCRIPTION:

This directive obtains a variable size segment from the region specified by `id`. The address of the allocated segment is returned in `segment`. The `RTEMS_WAIT` and `RTEMS_NO_WAIT` components of the options parameter are used to specify whether the calling tasks wish to wait for a segment to become available or return immediately if no segment is available. For either option, if a sufficiently sized segment is available, then the segment is successfully acquired by returning immediately with the `RTEMS_SUCCESSFUL` status code.

If the calling task chooses to return immediately and a segment large enough is not available, then an error code indicating this fact is returned. If the calling task chooses to wait for the segment and a segment large enough is not available, then the calling task is placed on the region's segment wait queue and blocked. If the region was created with the `RTEMS_PRIORITY` option, then the calling task is inserted into the wait queue according to its priority. However, if the region was created with the `RTEMS_FIFO` option, then the calling task is placed at the rear of the wait queue.

The timeout parameter specifies the maximum interval that a task is willing to wait to obtain a segment. If timeout is set to `RTEMS_NO_TIMEOUT`, then the calling task will wait forever.

NOTES:

The actual length of the allocated segment may be larger than the requested size because a segment size is always a multiple of the region's page size.

The following segment acquisition option constants are defined by RTEMS:

- `RTEMS_WAIT` - task will wait for segment (default)

- `RTEMS_NO_WAIT` - task should not wait

A clock tick is required to support the timeout functionality of this directive.

14.4.6 REGION_RETURN_SEGMENT - Return segment to a region

CALLING SEQUENCE:

```
rtems_status_code rtems_region_return_segment(  
    rtems_id id,  
    void *segment  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - segment returned successfully

RTEMS_INVALID_ADDRESS - `segment` is NULL

RTEMS_INVALID_ID - invalid region id

RTEMS_INVALID_ADDRESS - segment address not in region

DESCRIPTION:

This directive returns the segment specified by `segment` to the region specified by `id`. The returned segment is merged with its neighbors to form the largest possible segment. The first task on the wait queue is examined to determine if its segment request can now be satisfied. If so, it is given a segment and unblocked. This process is repeated until the first task's segment request cannot be satisfied.

NOTES:

This directive will cause the calling task to be preempted if one or more local tasks are waiting for a segment and the following conditions exist:

- a waiting task has a higher priority than the calling task
- the size of the segment required by the waiting task is less than or equal to the size of the segment returned.

14.4.7 REGION_GET_SEGMENT_SIZE - Obtain size of a segment

CALLING SEQUENCE:

```
rtcms_status_code rtcms_region_get_segment_size(
    rtcms_id id,
    void *segment,
    ssize_t *size
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - segment obtained successfully

RTEMS_INVALID_ADDRESS - `segment` is NULL

RTEMS_INVALID_ADDRESS - `size` is NULL

RTEMS_INVALID_ID - invalid region id

RTEMS_INVALID_ADDRESS - segment address not in region

DESCRIPTION:

This directive obtains the size in bytes of the specified segment.

NOTES:

The actual length of the allocated segment may be larger than the requested size because a segment size is always a multiple of the region's page size.

14.4.8 REGION_RESIZE_SEGMENT - Change size of a segment

CALLING SEQUENCE:

```
rtems_status_code rtems_region_resize_segment(  
    rtems_id      id,  
    void          *segment,  
    ssize_t       size,  
    ssize_t       *old_size  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - segment obtained successfully

RTEMS_INVALID_ADDRESS - `segment` is NULL

RTEMS_INVALID_ADDRESS - `old_size` is NULL

RTEMS_INVALID_ID - invalid region id

RTEMS_INVALID_ADDRESS - segment address not in region RTEMS_UNSATISFIED - unable to make segment larger

DESCRIPTION:

This directive is used to increase or decrease the size of a segment. When increasing the size of a segment, it is possible that there is not memory available contiguous to the segment. In this case, the request is unsatisfied.

NOTES:

If an attempt to increase the size of a segment fails, then the application may want to allocate a new segment of the desired size, copy the contents of the original segment to the new, larger segment and then return the original segment.

15 Dual-Ported Memory Manager

15.1 Introduction

The dual-ported memory manager provides a mechanism for converting addresses between internal and external representations for multiple dual-ported memory areas (DPMA). The directives provided by the dual-ported memory manager are:

- `rtems_port_create` - Create a port
- `rtems_port_ident` - Get ID of a port
- `rtems_port_delete` - Delete a port
- `rtems_port_external_to_internal` - Convert external to internal address
- `rtems_port_internal_to_external` - Convert internal to external address

15.2 Background

A dual-ported memory area (DPMA) is a contiguous block of RAM owned by a particular processor but which can be accessed by other processors in the system. The owner accesses the memory using internal addresses, while other processors must use external addresses. RTEMS defines a port as a particular mapping of internal and external addresses.

There are two system configurations in which dual-ported memory is commonly found. The first is tightly-coupled multiprocessor computer systems where the dual-ported memory is shared between all nodes and is used for inter-node communication. The second configuration is computer systems with intelligent peripheral controllers. These controllers typically utilize the DPMA for high-performance data transfers.

15.3 Operations

15.3.1 Creating a Port

The `rtems_port_create` directive creates a port into a DPMA with the user-defined name. The user specifies the association between internal and external representations for the port being created. RTEMS allocates a Dual-Ported Memory Control Block (DPCB) from the DPCB free list to maintain the newly created DPMA. RTEMS also generates a unique dual-ported memory port ID which is returned to the calling task. RTEMS does not initialize the dual-ported memory area or access any memory within it.

15.3.2 Obtaining Port IDs

When a port is created, RTEMS generates a unique port ID and assigns it to the created port until it is deleted. The port ID may be obtained by either of two methods. First, as the result of an invocation of the `rtems_port_create` directive, the task ID is stored in a user provided location. Second, the port ID may be obtained later using the `rtems_port_ident` directive. The port ID is used by other dual-ported memory manager directives to access this port.

15.3.3 Converting an Address

The `rtems_port_external_to_internal` directive is used to convert an address from external to internal representation for the specified port. The `rtems_port_internal_to_external` directive is used to convert an address from internal to external representation for the specified port. If an attempt is made to convert an address which lies outside the specified DPMA, then the address to be converted will be returned.

15.3.4 Deleting a DPMA Port

A port can be removed from the system and returned to RTEMS with the `rtems_port_delete` directive. When a port is deleted, its control block is returned to the DPCB free list.

15.4 Directives

This section details the dual-ported memory manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

15.4.1 PORT_CREATE - Create a port

CALLING SEQUENCE:

```
rtcms_status_code rtcms_port_create(  
    rtcms_name  name,  
    void        *internal_start,  
    void        *external_start,  
    uint32_t    length,  
    rtcms_id    *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - port created successfully

RTEMS_INVALID_NAME - invalid port name

RTEMS_INVALID_ADDRESS - address not on four byte boundary

RTEMS_INVALID_ADDRESS - id is NULL

RTEMS_TOO_MANY - too many DP memory areas created

DESCRIPTION:

This directive creates a port which resides on the local node for the specified DPMA. The assigned port id is returned in id. This port id is used as an argument to other dual-ported memory manager directives to convert addresses within this DPMA.

For control and maintenance of the port, RTEMS allocates and initializes an DPCB from the DPCB free pool. Thus memory from the dual-ported memory area is not used to store the DPCB.

NOTES:

The internal_address and external_address parameters must be on a four byte boundary.

This directive will not cause the calling task to be preempted.

15.4.2 PORT_IDENT - Get ID of a port

CALLING SEQUENCE:

```
rtcms_status_code rtcms_port_ident(  
    rtcms_name  name,  
    rtcms_id    *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - port identified successfully

RTEMS_INVALID_ADDRESS - id is NULL

RTEMS_INVALID_NAME - port name not found

DESCRIPTION:

This directive obtains the port id associated with the specified name to be acquired. If the port name is not unique, then the port id will match one of the DPMA's with that name. However, this port id is not guaranteed to correspond to the desired DPMA. The port id is used to access this DPMA in other dual-ported memory area related directives.

NOTES:

This directive will not cause the running task to be preempted.

15.4.3 PORT_DELETE - Delete a port

CALLING SEQUENCE:

```
rtcms_status_code rtcms_port_delete(  
    rtcms_id id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - port deleted successfully

RTEMS_INVALID_ID - invalid port id

DESCRIPTION:

This directive deletes the dual-ported memory area specified by id. The DPCB for the deleted dual-ported memory area is reclaimed by RTEMS.

NOTES:

This directive will not cause the calling task to be preempted.

The calling task does not have to be the task that created the port. Any local task that knows the port id can delete the port.

15.4.4 PORT_EXTERNAL_TO_INTERNAL - Convert external to internal address

CALLING SEQUENCE:

```
rtems_status_code rtems_port_external_to_internal(  
    rtems_id    id,  
    void        *external,  
    void        **internal  
);
```

DIRECTIVE STATUS CODES:

RTEMS_INVALID_ADDRESS - internal is NULL

RTEMS_SUCCESSFUL - successful conversion

DESCRIPTION:

This directive converts a dual-ported memory address from external to internal representation for the specified port. If the given external address is invalid for the specified port, then the internal address is set to the given external address.

NOTES:

This directive is callable from an ISR.

This directive will not cause the calling task to be preempted.

15.4.5 PORT_INTERNAL_TO_EXTERNAL - Convert internal to external address

CALLING SEQUENCE:

```
rtcms_status_code rtcms_port_internal_to_external(  
    rtcms_id    id,  
    void        *internal,  
    void        **external  
);
```

DIRECTIVE STATUS CODES:

RTEMS_INVALID_ADDRESS - external is NULL

RTEMS_SUCCESSFUL - successful conversion

DESCRIPTION:

This directive converts a dual-ported memory address from internal to external representation so that it can be passed to owner of the DPMA represented by the specified port. If the given internal address is an invalid dual-ported address, then the external address is set to the given internal address.

NOTES:

This directive is callable from an ISR.

This directive will not cause the calling task to be preempted.

16 I/O Manager

16.1 Introduction

The input/output interface manager provides a well-defined mechanism for accessing device drivers and a structured methodology for organizing device drivers. The directives provided by the I/O manager are:

- `rtems_io_initialize` - Initialize a device driver
- `rtems_io_register_driver` - Register a device driver
- `rtems_io_unregister_driver` - Unregister a device driver
- `rtems_io_register_name` - Register a device name
- `rtems_io_lookup_name` - Look up a device name
- `rtems_io_open` - Open a device
- `rtems_io_close` - Close a device
- `rtems_io_read` - Read from a device
- `rtems_io_write` - Write to a device
- `rtems_io_control` - Special device services

16.2 Background

16.2.1 Device Driver Table

Each application utilizing the RTEMS I/O manager must specify the address of a Device Driver Table in its Configuration Table. This table contains each device driver's entry points that is to be initialised by RTEMS during initialization. Each device driver may contain the following entry points:

- Initialization
- Open
- Close
- Read
- Write
- Control

If the device driver does not support a particular entry point, then that entry in the Configuration Table should be NULL. RTEMS will return `RTEMS_SUCCESSFUL` as the executive's and zero (0) as the device driver's return code for these device driver entry points.

Applications can register and unregister drivers with the RTEMS I/O manager avoiding the need to have all drivers statically defined and linked into this table.

The '`confdefs.h`' entry `CONFIGURE_MAXIMUM_DRIVERS` configures the number of driver slots available to the application.

16.2.2 Major and Minor Device Numbers

Each call to the I/O manager must provide a device's major and minor numbers as arguments. The major number is the index of the requested driver's entry points in the Device Driver Table, and is used to select a specific device driver. The exact usage of the minor number is driver specific, but is commonly used to distinguish between a number of devices controlled by the same driver.

The data types `rtems_device_major_number` and `rtems_device_minor_number` are used to manipulate device major and minor numbers, respectively.

16.2.3 Device Names

The I/O Manager provides facilities to associate a name with a particular device. Directives are provided to register the name of a device and to look up the major/minor number pair associated with a device name.

16.2.4 Device Driver Environment

Application developers, as well as device driver developers, must be aware of the following regarding the RTEMS I/O Manager:

- A device driver routine executes in the context of the invoking task. Thus if the driver blocks, the invoking task blocks.
- The device driver is free to change the modes of the invoking task, although the driver should restore them to their original values.
- Device drivers may be invoked from ISRs.
- Only local device drivers are accessible through the I/O manager.
- A device driver routine may invoke all other RTEMS directives, including I/O directives, on both local and global objects.

Although the RTEMS I/O manager provides a framework for device drivers, it makes no assumptions regarding the construction or operation of a device driver.

16.2.5 Runtime Driver Registration

Board support package and application developers can select whether a device driver is statically entered into the default device table or registered at runtime.

Dynamic registration helps applications where:

1. The BSP and kernel libraries are common to a range of applications for a specific target platform. An application may be built upon a common library with all drivers. The application selects and registers the drivers. Uniform driver name lookup protects the application.
2. The type and range of drivers may vary as the application probes a bus during initialization.
3. Support for hot swap bus system such as Compact PCI.
4. Support for runtime loadable driver modules.

16.2.6 Device Driver Interface

When an application invokes an I/O manager directive, RTEMS determines which device driver entry point must be invoked. The information passed by the application to RTEMS is then passed to the correct device driver entry point. RTEMS will invoke each device driver entry point assuming it is compatible with the following prototype:

```
rtems_device_driver io_entry(
    rtems_device_major_number  major,
    rtems_device_minor_number  minor,
    void                       *argument_block
);
```

The format and contents of the parameter block are device driver and entry point dependent.

It is recommended that a device driver avoid generating error codes which conflict with those used by application components. A common technique used to generate driver specific error codes is to make the most significant part of the status indicate a driver specific code.

16.2.7 Device Driver Initialization

RTEMS automatically initializes all device drivers when multitasking is initiated via the `rtems_initialize_executive` directive. RTEMS initializes the device drivers by invoking each device driver initialization entry point with the following parameters:

major	the major device number for this device driver.
minor	zero.
argument_block	will point to the Configuration Table.

The returned status will be ignored by RTEMS. If the driver cannot successfully initialize the device, then it should invoke the `fatal_error_occurred` directive.

16.3 Operations

16.3.1 Register and Lookup Name

The `rtems_io_register` directive associates a name with the specified device (i.e. major/minor number pair). Device names are typically registered as part of the device driver initialization sequence. The `rtems_io_lookup` directive is used to determine the major/minor number pair associated with the specified device name. The use of these directives frees the application from being dependent on the arbitrary assignment of major numbers in a particular application. No device naming conventions are dictated by RTEMS.

16.3.2 Accessing an Device Driver

The I/O manager provides directives which enable the application program to utilize device drivers in a standard manner. There is a direct correlation between the RTEMS I/O manager directives `rtems_io_initialize`, `rtems_io_open`, `rtems_io_close`, `rtems_io_read`, `rtems_io_write`, and `rtems_io_control` and the underlying device driver entry points.

16.4 Directives

This section details the I/O manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

16.4.1 IO_REGISTER_DRIVER - Register a device driver

CALLING SEQUENCE:

```
rtems_status_code rtems_io_register_driver(  
    rtems_device_major_number    major,  
    rtems_driver_address_table *driver_table,  
    rtems_device_major_number    *registered_major  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - successfully registered
RTEMS_INVALID_ADDRESS - invalid registered major pointer
RTEMS_INVALID_ADDRESS - invalid driver table
RTEMS_INVALID_NUMBER - invalid major device number
RTEMS_TOO_MANY - no available major device table slot
RTEMS_RESOURCE_IN_USE - major device number entry in use

DESCRIPTION:

This directive attempts to add a new device driver to the Device Driver Table. The user can specify a specific major device number via the directive's **major** parameter, or let the registration routine find the next available major device number by specifying a major number of 0. The selected major device number is returned via the **registered_major** directive parameter. The directive automatically allocation major device numbers from the highest value down.

This directive automatically invokes the IO_INITIALIZE directive if the driver address table has an initialization and open entry.

The directive returns RTEMS_TOO_MANY if Device Driver Table is full, and RTEMS_RESOURCE_IN_USE if a specific major device number is requested and it is already in use.

NOTES:

The Device Driver Table size is specified in the Configuration Table configuration. This needs to be set to maximum size the application requires.

16.4.2 IO_UNREGISTER_DRIVER - Unregister a device driver

CALLING SEQUENCE:

```
    rtems_status_code rtems_io_unregister_driver(  
        rtems_device_major_number    major  
    );
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - successfully registered

RTEMS_INVALID_NUMBER - invalid major device number

DESCRIPTION:

This directive removes a device driver from the Device Driver Table.

NOTES:

Currently no specific checks are made and the driver is not closed.

16.4.3 IO_INITIALIZE - Initialize a device driver

CALLING SEQUENCE:

```
rtems_status_code rtems_io_initialize(  
    rtems_device_major_number  major,  
    rtems_device_minor_number  minor,  
    void                      *argument  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - successfully initialized

RTEMS_INVALID_NUMBER - invalid major device number

DESCRIPTION:

This directive calls the device driver initialization routine specified in the Device Driver Table for this major number. This directive is automatically invoked for each device driver when multitasking is initiated via the `initialize_executive` directive.

A device driver initialization module is responsible for initializing all hardware and data structures associated with a device. If necessary, it can allocate memory to be used during other operations.

NOTES:

This directive may or may not cause the calling task to be preempted. This is dependent on the device driver being initialized.

16.4.4 IO_REGISTER_NAME - Register a device

CALLING SEQUENCE:

```
rtcms_status_code rtcms_io_register_name(  
    const char          *name,  
    rtcms_device_major_number  major,  
    rtcms_device_minor_number  minor  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - successfully initialized

RTEMS_TOO_MANY - too many devices registered

DESCRIPTION:

This directive associates name with the specified major/minor number pair.

NOTES:

This directive will not cause the calling task to be preempted.

16.4.5 IO_LOOKUP_NAME - Lookup a device

CALLING SEQUENCE:

```
rtems_status_code rtems_io_lookup_name(  
    const char          *name,  
    rtems_driver_name_t *device_info  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - successfully initialized

RTEMS_UNSATISFIED - name not registered

DESCRIPTION:

This directive returns the major/minor number pair associated with the given device name in `device_info`.

NOTES:

This directive will not cause the calling task to be preempted.

16.4.6 IO_OPEN - Open a device

CALLING SEQUENCE:

```
rtcms_status_code rtcms_io_open(  
    rtcms_device_major_number  major,  
    rtcms_device_minor_number  minor,  
    void                        *argument  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - successfully initialized

RTEMS_INVALID_NUMBER - invalid major device number

DESCRIPTION:

This directive calls the device driver open routine specified in the Device Driver Table for this major number. The open entry point is commonly used by device drivers to provide exclusive access to a device.

NOTES:

This directive may or may not cause the calling task to be preempted. This is dependent on the device driver being invoked.

16.4.7 IO_CLOSE - Close a device

CALLING SEQUENCE:

```
rtcms_status_code rtcms_io_close(  
    rtcms_device_major_number  major,  
    rtcms_device_minor_number  minor,  
    void                       *argument  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - successfully initialized

RTEMS_INVALID_NUMBER - invalid major device number

DESCRIPTION:

This directive calls the device driver close routine specified in the Device Driver Table for this major number. The close entry point is commonly used by device drivers to relinquish exclusive access to a device.

NOTES:

This directive may or may not cause the calling task to be preempted. This is dependent on the device driver being invoked.

16.4.8 IO_READ - Read from a device

CALLING SEQUENCE:

```
rtems_status_code rtems_io_read(  
    rtems_device_major_number  major,  
    rtems_device_minor_number  minor,  
    void                       *argument  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - successfully initialized

RTEMS_INVALID_NUMBER - invalid major device number

DESCRIPTION:

This directive calls the device driver read routine specified in the Device Driver Table for this major number. Read operations typically require a buffer address as part of the argument parameter block. The contents of this buffer will be replaced with data from the device.

NOTES:

This directive may or may not cause the calling task to be preempted. This is dependent on the device driver being invoked.

16.4.9 IO_WRITE - Write to a device

CALLING SEQUENCE:

```
rtcms_status_code rtcms_io_write(  
    rtcms_device_major_number  major,  
    rtcms_device_minor_number  minor,  
    void                        *argument  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - successfully initialized

RTEMS_INVALID_NUMBER - invalid major device number

DESCRIPTION:

This directive calls the device driver write routine specified in the Device Driver Table for this major number. Write operations typically require a buffer address as part of the argument parameter block. The contents of this buffer will be sent to the device.

NOTES:

This directive may or may not cause the calling task to be preempted. This is dependent on the device driver being invoked.

16.4.10 IO_CONTROL - Special device services

CALLING SEQUENCE:

```
rtcms_status_code rtcms_io_control(  
    rtcms_device_major_number  major,  
    rtcms_device_minor_number  minor,  
    void                       *argument  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - successfully initialized

RTEMS_INVALID_NUMBER - invalid major device number

DESCRIPTION:

This directive calls the device driver I/O control routine specified in the Device Driver Table for this major number. The exact functionality of the driver entry called by this directive is driver dependent. It should not be assumed that the control entries of two device drivers are compatible. For example, an RS-232 driver I/O control operation may change the baud rate of a serial line, while an I/O control operation for a floppy disk driver may cause a seek operation.

NOTES:

This directive may or may not cause the calling task to be preempted. This is dependent on the device driver being invoked.

17 Fatal Error Manager

17.1 Introduction

The fatal error manager processes all fatal or irrecoverable errors. The directive provided by the fatal error manager is:

- `rtems_fatal_error_occurred` - Invoke the fatal error handler

17.2 Background

The fatal error manager is called upon detection of an irrecoverable error condition by either RTEMS or the application software. Fatal errors can be detected from three sources:

- the executive (RTEMS)
- user system code
- user application code

RTEMS automatically invokes the fatal error manager upon detection of an error it considers to be fatal. Similarly, the user should invoke the fatal error manager upon detection of a fatal error.

Each status or dynamic user extension set may include a fatal error handler. The fatal error handler in the static extension set can be used to provide access to debuggers and monitors which may be present on the target hardware. If any user-supplied fatal error handlers are installed, the fatal error manager will invoke them. If no user handlers are configured or if all the user handler return control to the fatal error manager, then the RTEMS default fatal error handler is invoked. If the default fatal error handler is invoked, then the system state is marked as failed.

Although the precise behavior of the default fatal error handler is processor specific, in general, it will disable all maskable interrupts, place the error code in a known processor dependent place (generally either on the stack or in a register), and halt the processor. The precise actions of the RTEMS fatal error are discussed in the Default Fatal Error Processing chapter of the Applications Supplement document for a specific target processor.

17.3 Operations

17.3.1 Announcing a Fatal Error

The `rtems_fatal_error_occurred` directive is invoked when a fatal error is detected. Before invoking any user-supplied fatal error handlers or the RTEMS fatal error handler, the `rtems_fatal_error_occurred` directive stores useful information in the variable `_Internal_errors_What_happened`. This structure contains three pieces of information:

- the source of the error (API or executive core),
- whether the error was generated internally by the executive, and a
- a numeric code to indicate the error type.

The error type indicator is dependent on the source of the error and whether or not the error was internally generated by the executive. If the error was generated from an API, then the error code will be of that API's error or status codes. The status codes for the RTEMS API are in `cpukit/rtems/include/rtems/rtems/status.h`. Those for the POSIX API can be found in `<errno.h>`.

The `rtems_fatal_error_occurred` directive is responsible for invoking an optional user-supplied fatal error handler and/or the RTEMS fatal error handler. All fatal error handlers are passed an error code to describe the error detected.

Occasionally, an application requires more sophisticated fatal error processing such as passing control to a debugger. For these cases, a user-supplied fatal error handler can be specified in the RTEMS configuration table. The User Extension Table field `fatal` contains the address of the fatal error handler to be executed when the `rtems_fatal_error_occurred` directive is called. If the field is set to `NULL` or if the configured fatal error handler returns to the executive, then the default handler provided by RTEMS is executed. This default handler will halt execution on the processor where the error occurred.

17.4 Directives

This section details the fatal error manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

17.4.1 FATAL_ERROR_OCCURRED - Invoke the fatal error handler

CALLING SEQUENCE:

```
void volatile rtems_fatal_error_occurred(  
    uint32_t the_error  
);
```

DIRECTIVE STATUS CODES

NONE

DESCRIPTION:

This directive processes fatal errors. If the FATAL error extension is defined in the configuration table, then the user-defined error extension is called. If configured and the provided FATAL error extension returns, then the RTEMS default error handler is invoked. This directive can be invoked by RTEMS or by the user's application code including initialization tasks, other tasks, and ISRs.

NOTES:

This directive supports local operations only.

Unless the user-defined error extension takes special actions such as restarting the calling task, this directive WILL NOT RETURN to the caller.

The user-defined extension for this directive may wish to initiate a global shutdown.

18 Scheduling Concepts

18.1 Introduction

The concept of scheduling in real-time systems dictates the ability to provide immediate response to specific external events, particularly the necessity of scheduling tasks to run within a specified time limit after the occurrence of an event. For example, software embedded in life-support systems used to monitor hospital patients must take instant action if a change in the patient's status is detected.

The component of RTEMS responsible for providing this capability is appropriately called the scheduler. The scheduler's sole purpose is to allocate the all important resource of processor time to the various tasks competing for attention. The RTEMS scheduler allocates the processor using a priority-based, preemptive algorithm augmented to provide round-robin characteristics within individual priority groups. The goal of this algorithm is to guarantee that the task which is executing on the processor at any point in time is the one with the highest priority among all tasks in the ready state.

There are two common methods of accomplishing the mechanics of this algorithm. Both ways involve a list or chain of tasks in the ready state. One method is to randomly place tasks in the ready chain forcing the scheduler to scan the entire chain to determine which task receives the processor. The other method is to schedule the task by placing it in the proper place on the ready chain based on the designated scheduling criteria at the time it enters the ready state. Thus, when the processor is free, the first task on the ready chain is allocated the processor. RTEMS schedules tasks using the second method to guarantee faster response times to external events.

18.2 Scheduling Mechanisms

RTEMS provides four mechanisms which allow the user to impact the task scheduling process:

- user-selectable task priority level
- task preemption control
- task timeslicing control
- manual round-robin selection

Each of these methods provides a powerful capability to customize sets of tasks to satisfy the unique and particular requirements encountered in custom real-time applications. Although each mechanism operates independently, there is a precedence relationship which governs the effects of scheduling modifications. The evaluation order for scheduling characteristics is always priority, preemption mode, and timeslicing. When reading the descriptions of timeslicing and manual round-robin it is important to keep in mind that preemption (if enabled) of a task by higher priority tasks will occur as required, overriding the other factors presented in the description.

18.2.1 Task Priority and Scheduling

The most significant of these mechanisms is the ability for the user to assign a priority level to each individual task when it is created and to alter a task's priority at run-time. RTEMS

provides 255 priority levels. Level 255 is the lowest priority and level 1 is the highest. When a task is added to the ready chain, it is placed behind all other tasks of the same priority. This rule provides a round-robin within priority group scheduling characteristic. This means that in a group of equal priority tasks, tasks will execute in the order they become ready or FIFO order. Even though there are ways to manipulate and adjust task priorities, the most important rule to remember is:

The RTEMS scheduler will always select the highest priority task that is ready to run when allocating the processor to a task.

18.2.2 Preemption

Another way the user can alter the basic scheduling algorithm is by manipulating the preemption mode flag (`RTEMS_PREEMPT_MASK`) of individual tasks. If preemption is disabled for a task (`RTEMS_NO_PREEMPT`), then the task will not relinquish control of the processor until it terminates, blocks, or re-enables preemption. Even tasks which become ready to run and possess higher priority levels will not be allowed to execute. Note that the preemption setting has no effect on the manner in which a task is scheduled. It only applies once a task has control of the processor.

18.2.3 Timeslicing

Timeslicing or round-robin scheduling is an additional method which can be used to alter the basic scheduling algorithm. Like preemption, timeslicing is specified on a task by task basis using the timeslicing mode flag (`RTEMS_TIMESLICE_MASK`). If timeslicing is enabled for a task (`RTEMS_TIMESLICE`), then RTEMS will limit the amount of time the task can execute before the processor is allocated to another task. Each tick of the real-time clock reduces the currently running task's timeslice. When the execution time equals the timeslice, RTEMS will dispatch another task of the same priority to execute. If there are no other tasks of the same priority ready to execute, then the current task is allocated an additional timeslice and continues to run. Remember that a higher priority task will preempt the task (unless preemption is disabled) as soon as it is ready to run, even if the task has not used up its entire timeslice.

18.2.4 Manual Round-Robin

The final mechanism for altering the RTEMS scheduling algorithm is called manual round-robin. Manual round-robin is invoked by using the `rtems_task_wake_after` directive with a time interval of `RTEMS_YIELD_PROCESSOR`. This allows a task to give up the processor and be immediately returned to the ready chain at the end of its priority group. If no other tasks of the same priority are ready to run, then the task does not lose control of the processor.

18.2.5 Dispatching Tasks

The dispatcher is the RTEMS component responsible for allocating the processor to a ready task. In order to allocate the processor to one task, it must be deallocated or retrieved from the task currently using it. This involves a concept called a context switch. To perform a context switch, the dispatcher saves the context of the current task and restores the context of the task which has been allocated to the processor. Saving and restoring a task's context is the storing/loading of all the essential information about a task to enable it to continue

execution without any effects of the interruption. For example, the contents of a task's register set must be the same when it is given the processor as they were when it was taken away. All of the information that must be saved or restored for a context switch is located either in the TCB or on the task's stacks.

Tasks that utilize a numeric coprocessor and are created with the `RTEMS_FLOATING_POINT` attribute require additional operations during a context switch. These additional operations are necessary to save and restore the floating point context of `RTEMS_FLOATING_POINT` tasks. To avoid unnecessary save and restore operations, the state of the numeric coprocessor is only saved when a `RTEMS_FLOATING_POINT` task is dispatched and that task was not the last task to utilize the coprocessor.

18.3 Task State Transitions

Tasks in an RTEMS system must always be in one of the five allowable task states. These states are: executing, ready, blocked, dormant, and non-existent.

A task occupies the non-existent state before a `rtems_task_create` has been issued on its behalf. A task enters the non-existent state from any other state in the system when it is deleted with the `rtems_task_delete` directive. While a task occupies this state it does not have a TCB or a task ID assigned to it; therefore, no other tasks in the system may reference this task.

When a task is created via the `rtems_task_create` directive it enters the dormant state. This state is not entered through any other means. Although the task exists in the system, it cannot actively compete for system resources. It will remain in the dormant state until it is started via the `rtems_task_start` directive, at which time it enters the ready state. The task is now permitted to be scheduled for the processor and to compete for other system resources.

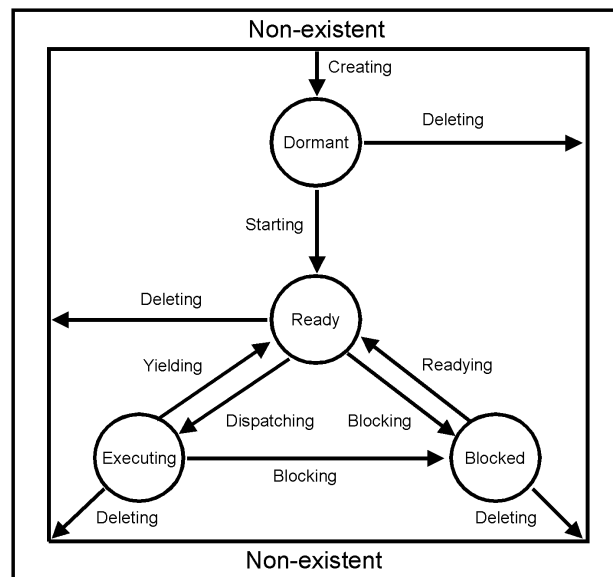

Figure 18.1: RTEMS Task States

A task occupies the blocked state whenever it is unable to be scheduled to run. A running task may block itself or be blocked by other tasks in the system. The running task blocks itself through voluntary operations that cause the task to wait. The only way a task can block a task other than itself is with the `rtems_task_suspend` directive. A task enters the blocked state due to any of the following conditions:

- A task issues a `rtems_task_suspend` directive which blocks either itself or another task in the system.
- The running task issues a `rtems_message_queue_receive` directive with the wait option and the message queue is empty.
- The running task issues an `rtems_event_receive` directive with the wait option and the currently pending events do not satisfy the request.
- The running task issues a `rtems_semaphore_obtain` directive with the wait option and the requested semaphore is unavailable.
- The running task issues a `rtems_task_wake_after` directive which blocks the task for the given time interval. If the time interval specified is zero, the task yields the processor and remains in the ready state.
- The running task issues a `rtems_task_wake_when` directive which blocks the task until the requested date and time arrives.
- The running task issues a `rtems_region_get_segment` directive with the wait option and there is not an available segment large enough to satisfy the task's request.
- The running task issues a `rtems_rate_monotonic_period` directive and must wait for the specified rate monotonic period to conclude.

A blocked task may also be suspended. Therefore, both the suspension and the blocking condition must be removed before the task becomes ready to run again.

A task occupies the ready state when it is able to be scheduled to run, but currently does not have control of the processor. Tasks of the same or higher priority will yield the processor by either becoming blocked, completing their timeslice, or being deleted. All tasks with the same priority will execute in FIFO order. A task enters the ready state due to any of the following conditions:

- A running task issues a `rtems_task_resume` directive for a task that is suspended and the task is not blocked waiting on any resource.
- A running task issues a `rtems_message_queue_send`, `rtems_message_queue_broadcast`, or a `rtems_message_queue_urgent` directive which posts a message to the queue on which the blocked task is waiting.
- A running task issues an `rtems_event_send` directive which sends an event condition to a task which is blocked waiting on that event condition.
- A running task issues a `rtems_semaphore_release` directive which releases the semaphore on which the blocked task is waiting.
- A timeout interval expires for a task which was blocked by a call to the `rtems_task_wake_after` directive.
- A timeout period expires for a task which blocked by a call to the `rtems_task_wake_when` directive.

- A running task issues a `rtems_region_return_segment` directive which releases a segment to the region on which the blocked task is waiting and a resulting segment is large enough to satisfy the task's request.
- A rate monotonic period expires for a task which blocked by a call to the `rtems_rate_monotonic_period` directive.
- A timeout interval expires for a task which was blocked waiting on a message, event, semaphore, or segment with a timeout specified.
- A running task issues a directive which deletes a message queue, a semaphore, or a region on which the blocked task is waiting.
- A running task issues a `rtems_task_restart` directive for the blocked task.
- The running task, with its preemption mode enabled, may be made ready by issuing any of the directives that may unblock a task with a higher priority. This directive may be issued from the running task itself or from an ISR.

A ready task occupies the executing state when it has control of the CPU. A task enters the executing state due to any of the following conditions:

- The task is the highest priority ready task in the system.
- The running task blocks and the task is next in the scheduling queue. The task may be of equal priority as in round-robin scheduling or the task may possess the highest priority of the remaining ready tasks.
- The running task may reenables its preemption mode and a task exists in the ready queue that has a higher priority than the running task.
- The running task lowers its own priority and another task is of higher priority as a result.
- The running task raises the priority of a task above its own and the running task is in preemption mode.

19 Rate Monotonic Manager

19.1 Introduction

The rate monotonic manager provides facilities to implement tasks which execute in a periodic fashion. Critically, it also gathers information about the execution of those periods and can provide important statistics to the user which can be used to analyze and tune the application. The directives provided by the rate monotonic manager are:

- `rtems_rate_monotonic_create` - Create a rate monotonic period
- `rtems_rate_monotonic_ident` - Get ID of a period
- `rtems_rate_monotonic_cancel` - Cancel a period
- `rtems_rate_monotonic_delete` - Delete a rate monotonic period
- `rtems_rate_monotonic_period` - Conclude current/Start next period
- `rtems_rate_monotonic_get_status` - Obtain status from a period
- `rtems_rate_monotonic_get_statistics` - Obtain statistics from a period
- `rtems_rate_monotonic_reset_statistics` - Reset statistics for a period
- `rtems_rate_monotonic_reset_all_statistics` - Reset statistics for all periods
- `rtems_rate_monotonic_report_statistics` - Print period statistics report

19.2 Background

The rate monotonic manager provides facilities to manage the execution of periodic tasks. This manager was designed to support application designers who utilize the Rate Monotonic Scheduling Algorithm (RMS) to ensure that their periodic tasks will meet their deadlines, even under transient overload conditions. Although designed for hard real-time systems, the services provided by the rate monotonic manager may be used by any application which requires periodic tasks.

19.2.1 Rate Monotonic Manager Required Support

A clock tick is required to support the functionality provided by this manager.

19.2.2 Period Statistics

This manager maintains a set of statistics on each period. These statistics are reset implicitly at period creation time and may be reset or obtained at any time by the application. The following is a list of the information kept:

- `owner` is the id of the thread that owns this period.
- `count` is the total number of periods executed.
- `missed_count` is the number of periods that were missed.
- `min_cpu_time` is the minimum amount of CPU execution time consumed on any execution of the periodic loop.
- `max_cpu_time` is the maximum amount of CPU execution time consumed on any execution of the periodic loop.

- `total_cpu_time` is the total amount of CPU execution time consumed by executions of the periodic loop.
- `min_wall_time` is the minimum amount of wall time that passed on any execution of the periodic loop.
- `max_wall_time` is the maximum amount of wall time that passed on any execution of the periodic loop.
- `total_wall_time` is the total amount of wall time that passed during executions of the periodic loop.

The period statistics information is inexpensive to maintain and can provide very useful insights into the execution characteristics of a periodic task loop. But it is just information. The period statistics reported must be analyzed by the user in terms of what the applications is. For example, in an application where priorities are assigned by the Rate Monotonic Algorithm, it would be very undesirable for high priority (i.e. frequency) tasks to miss their period. Similarly, in nearly any application, if a task were supposed to execute its periodic loop every 10 milliseconds and it averaged 11 milliseconds, then application requirements are not being met.

The information reported can be used to determine the "hot spots" in the application. Given a period's id, the user can determine the length of that period. From that information and the CPU usage, the user can calculate the percentage of CPU time consumed by that periodic task. For example, a task executing for 20 milliseconds every 200 milliseconds is consuming 10 percent of the processor's execution time. This is usually enough to make it a good candidate for optimization.

However, execution time alone is not enough to gauge the value of optimizing a particular task. It is more important to optimize a task executing 2 millisecond every 10 milliseconds (20 percent of the CPU) than one executing 10 milliseconds every 100 (10 percent of the CPU). As a general rule of thumb, the higher frequency at which a task executes, the more important it is to optimize that task.

19.2.3 Rate Monotonic Manager Definitions

A periodic task is one which must be executed at a regular interval. The interval between successive iterations of the task is referred to as its period. Periodic tasks can be characterized by the length of their period and execution time. The period and execution time of a task can be used to determine the processor utilization for that task. Processor utilization is the percentage of processor time used and can be calculated on a per-task or system-wide basis. Typically, the task's worst-case execution time will be less than its period. For example, a periodic task's requirements may state that it should execute for 10 milliseconds every 100 milliseconds. Although the execution time may be the average, worst, or best case, the worst-case execution time is more appropriate for use when analyzing system behavior under transient overload conditions.

In contrast, an aperiodic task executes at irregular intervals and has only a soft deadline. In other words, the deadlines for aperiodic tasks are not rigid, but adequate response times are desirable. For example, an aperiodic task may process user input from a terminal.

Finally, a sporadic task is an aperiodic task with a hard deadline and minimum interarrival time. The minimum interarrival time is the minimum period of time which exists between

successive iterations of the task. For example, a sporadic task could be used to process the pressing of a fire button on a joystick. The mechanical action of the fire button ensures a minimum time period between successive activations, but the missile must be launched by a hard deadline.

19.2.4 Rate Monotonic Scheduling Algorithm

The Rate Monotonic Scheduling Algorithm (RMS) is important to real-time systems designers because it allows one to guarantee that a set of tasks is schedulable. A set of tasks is said to be schedulable if all of the tasks can meet their deadlines. RMS provides a set of rules which can be used to perform a guaranteed schedulability analysis for a task set. This analysis determines whether a task set is schedulable under worst-case conditions and emphasizes the predictability of the system's behavior. It has been proven that:

RMS is an optimal static priority algorithm for scheduling independent, pre-emptible, periodic tasks on a single processor.

RMS is optimal in the sense that if a set of tasks can be scheduled by any static priority algorithm, then RMS will be able to schedule that task set. RMS bases its schedulability analysis on the processor utilization level below which all deadlines can be met.

RMS calls for the static assignment of task priorities based upon their period. The shorter a task's period, the higher its priority. For example, a task with a 1 millisecond period has higher priority than a task with a 100 millisecond period. If two tasks have the same period, then RMS does not distinguish between the tasks. However, RTEMS specifies that when given tasks of equal priority, the task which has been ready longest will execute first. RMS's priority assignment scheme does not provide one with exact numeric values for task priorities. For example, consider the following task set and priority assignments:

Task	Period (in milliseconds)	Priority
1	100	Low
2	50	Medium
3	50	Medium
4	25	High

RMS only calls for task 1 to have the lowest priority, task 4 to have the highest priority, and tasks 2 and 3 to have an equal priority between that of tasks 1 and 4. The actual RTEMS priorities assigned to the tasks must only adhere to those guidelines.

Many applications have tasks with both hard and soft deadlines. The tasks with hard deadlines are typically referred to as the critical task set, with the soft deadline tasks being the non-critical task set. The critical task set can be scheduled using RMS, with the non-critical tasks not executing under transient overload, by simply assigning priorities such that the lowest priority critical task (i.e. longest period) has a higher priority than the highest priority non-critical task. Although RMS may be used to assign priorities to the non-critical tasks, it is not necessary. In this instance, schedulability is only guaranteed for the critical task set.

19.2.5 Schedulability Analysis

RMS allows application designers to ensure that tasks can meet all deadlines, even under transient overload, without knowing exactly when any given task will execute by applying proven schedulability analysis rules.

19.2.5.1 Assumptions

The schedulability analysis rules for RMS were developed based on the following assumptions:

- The requests for all tasks for which hard deadlines exist are periodic, with a constant interval between requests.
- Each task must complete before the next request for it occurs.
- The tasks are independent in that a task does not depend on the initiation or completion of requests for other tasks.
- The execution time for each task without preemption or interruption is constant and does not vary.
- Any non-periodic tasks in the system are special. These tasks displace periodic tasks while executing and do not have hard, critical deadlines.

Once the basic schedulability analysis is understood, some of the above assumptions can be relaxed and the side-effects accounted for.

19.2.5.2 Processor Utilization Rule

The Processor Utilization Rule requires that processor utilization be calculated based upon the period and execution time of each task. The fraction of processor time spent executing task index is $\text{Time}(\text{index}) / \text{Period}(\text{index})$. The processor utilization can be calculated as follows:

```
Utilization = 0
```

```
for index = 1 to maximum_tasks
```

```
    Utilization = Utilization + (Time(index)/Period(index))
```

To ensure schedulability even under transient overload, the processor utilization must adhere to the following rule:

```
Utilization = maximum_tasks * (2**(1/maximum_tasks) - 1)
```

As the number of tasks increases, the above formula approaches $\ln(2)$ for a worst-case utilization factor of approximately 0.693. Many tasks sets can be scheduled with a greater utilization factor. In fact, the average processor utilization threshold for a randomly generated task set is approximately 0.88.

19.2.5.3 Processor Utilization Rule Example

This example illustrates the application of the Processor Utilization Rule to an application with three critical periodic tasks. The following table details the RMS priority, period, execution time, and processor utilization for each task:

Task	RMS Priority	Period	Execution Time	Processor Utilization
1	High	100	15	0.15
2	Medium	200	50	0.25
3	Low	300	100	0.33

The total processor utilization for this task set is 0.73 which is below the upper bound of $3 * (2^{1/3} - 1)$, or 0.779, imposed by the Processor Utilization Rule. Therefore, this task set is guaranteed to be schedulable using RMS.

19.2.5.4 First Deadline Rule

If a given set of tasks do exceed the processor utilization upper limit imposed by the Processor Utilization Rule, they can still be guaranteed to meet all their deadlines by application of the First Deadline Rule. This rule can be stated as follows:

For a given set of independent periodic tasks, if each task meets its first deadline when all tasks are started at the same time, then the deadlines will always be met for any combination of start times.

A key point with this rule is that ALL periodic tasks are assumed to start at the exact same instant in time. Although this assumption may seem to be invalid, RTEMS makes it quite easy to ensure. By having a non-preemptible user initialization task, all application tasks, regardless of priority, can be created and started before the initialization deletes itself. This technique ensures that all tasks begin to compete for execution time at the same instant – when the user initialization task deletes itself.

19.2.5.5 First Deadline Rule Example

The First Deadline Rule can ensure schedulability even when the Processor Utilization Rule fails. The example below is a modification of the Processor Utilization Rule example where task execution time has been increased from 15 to 25 units. The following table details the RMS priority, period, execution time, and processor utilization for each task:

Task	RMS Priority	Period	Execution Time	Processor Utilization
1	High	100	25	0.25
2	Medium	200	50	0.25
3	Low	300	100	0.33

The total processor utilization for the modified task set is 0.83 which is above the upper bound of $3 * (2^{1/3} - 1)$, or 0.779, imposed by the Processor Utilization Rule. Therefore, this task set is not guaranteed to be schedulable using RMS. However, the First Deadline Rule can guarantee the schedulability of this task set. This rule calls for one to examine each occurrence of deadline until either all tasks have met their deadline or one task failed to meet its first deadline. The following table details the time of each deadline occurrence, the maximum number of times each task may have run, the total execution time, and whether all the deadlines have been met.

Deadline Time	Task 1	Task 2	Task 3	Total Execution Time	All Deadlines Net?
100	1	1	1	$25 + 50 + 100 = 175$	NO
200	2	1	1	$50 + 50 + 100 = 200$	YES

The key to this analysis is to recognize when each task will execute. For example at time 100, task 1 must have met its first deadline, but tasks 2 and 3 may also have begun execution. In this example, at time 100 tasks 1 and 2 have completed execution and thus have met their first deadline. Tasks 1 and 2 have used $(25 + 50) = 75$ time units, leaving $(100 - 75) = 25$ time units for task 3 to begin. Because task 3 takes 100 ticks to execute, it will not have completed execution at time 100. Thus at time 100, all of the tasks except task 3 have met their first deadline.

At time 200, task 1 must have met its second deadline and task 2 its first deadline. As a result, of the first 200 time units, task 1 uses $(2 * 25) = 50$ and task 2 uses 50, leaving $(200 - 100)$ time units for task 3. Task 3 requires 100 time units to execute, thus it will have completed execution at time 200. Thus, all of the tasks have met their first deadlines at time 200, and the task set is schedulable using the First Deadline Rule.

19.2.5.6 Relaxation of Assumptions

The assumptions used to develop the RMS schedulability rules are uncommon in most real-time systems. For example, it was assumed that tasks have constant unvarying execution time. It is possible to relax this assumption, simply by using the worst-case execution time of each task.

Another assumption is that the tasks are independent. This means that the tasks do not wait for one another or contend for resources. This assumption can be relaxed by accounting for the amount of time a task spends waiting to acquire resources. Similarly, each task's execution time must account for any I/O performed and any RTEMS directive calls.

In addition, the assumptions did not account for the time spent executing interrupt service routines. This can be accounted for by including all the processor utilization by interrupt service routines in the utilization calculation. Similarly, one should also account for the impact of delays in accessing local memory caused by direct memory access and other processors accessing local dual-ported memory.

The assumption that nonperiodic tasks are used only for initialization or failure-recovery can be relaxed by placing all periodic tasks in the critical task set. This task set can be scheduled and analyzed using RMS. All nonperiodic tasks are placed in the non-critical task set. Although the critical task set can be guaranteed to execute even under transient overload, the non-critical task set is not guaranteed to execute.

In conclusion, the application designer must be fully cognizant of the system and its run-time behavior when performing schedulability analysis for a system using RMS. Every hardware and software factor which impacts the execution time of each task must be accounted for in the schedulability analysis.

19.3 Operations

19.3.1 Creating a Rate Monotonic Period

The `rtems_rate_monotonic_create` directive creates a rate monotonic period which is to be used by the calling task to delineate a period. RTEMS allocates a Period Control Block (PCB) from the PCB free list. This data structure is used by RTEMS to manage the newly created rate monotonic period. RTEMS returns a unique period ID to the application which is used by other rate monotonic manager directives to access this rate monotonic period.

19.3.2 Manipulating a Period

The `rtems_rate_monotonic_period` directive is used to establish and maintain periodic execution utilizing a previously created rate monotonic period. Once initiated by the `rtems_rate_monotonic_period` directive, the period is said to run until it either expires or is reinitiated. The state of the rate monotonic period results in one of the following scenarios:

- If the rate monotonic period is running, the calling task will be blocked for the remainder of the outstanding period and, upon completion of that period, the period will be reinitiated with the specified period.
- If the rate monotonic period is not currently running and has not expired, it is initiated with a length of period ticks and the calling task returns immediately.
- If the rate monotonic period has expired before the task invokes the `rtems_rate_monotonic_period` directive, the period will be initiated with a length of period ticks and the calling task returns immediately with a timeout error status.

19.3.3 Obtaining the Status of a Period

If the `rtems_rate_monotonic_period` directive is invoked with a period of `RTEMS_PERIOD_STATUS` ticks, the current state of the specified rate monotonic period will be returned. The following table details the relationship between the period's status and the directive status code returned by the `rtems_rate_monotonic_period` directive:

- `RTEMS_SUCCESSFUL` - period is running
- `RTEMS_TIMEOUT` - period has expired
- `RTEMS_NOT_DEFINED` - period has never been initiated

Obtaining the status of a rate monotonic period does not alter the state or length of that period.

19.3.4 Canceling a Period

The `rtems_rate_monotonic_cancel` directive is used to stop the period maintained by the specified rate monotonic period. The period is stopped and the rate monotonic period can be reinitiated using the `rtems_rate_monotonic_period` directive.

19.3.5 Deleting a Rate Monotonic Period

The `rtems_rate_monotonic_delete` directive is used to delete a rate monotonic period. If the period is running and has not expired, the period is automatically canceled. The rate monotonic period's control block is returned to the PCB free list when it is deleted. A rate monotonic period can be deleted by a task other than the task which created the period.

19.3.6 Examples

The following sections illustrate common uses of rate monotonic periods to construct periodic tasks.

19.3.7 Simple Periodic Task

This example consists of a single periodic task which, after initialization, executes every 100 clock ticks.

```

rtems_task Periodic_task(rtems_task_argument arg)
{
    rtems_name      name;
    rtems_id        period;
    rtems_status_code status;

    name = rtems_build_name( 'P', 'E', 'R', 'D' );

    status = rtems_rate_monotonic_create( name, &period );
    if ( status != RTEMS_STATUS_SUCCESSFUL ) {
        printf( "rtems_monotonic_create failed with status of %d.\n", rc );
        exit( 1 );
    }

    while ( 1 ) {
        if ( rtems_rate_monotonic_period( period, 100 ) == RTEMS_TIMEOUT )
            break;

        /* Perform some periodic actions */
    }

    /* missed period so delete period and SELF */

    status = rtems_rate_monotonic_delete( period );
    if ( status != RTEMS_STATUS_SUCCESSFUL ) {
        printf( "rtems_rate_monotonic_delete failed with status of %d.\n", status );
        exit( 1 );
    }

    status = rtems_task_delete( SELF );    /* should not return */
    printf( "rtems_task_delete returned with status of %d.\n", status );
    exit( 1 );
}

```

The above task creates a rate monotonic period as part of its initialization. The first time the loop is executed, the `rtems_rate_monotonic_period` directive will initiate the period for 100 ticks and return immediately. Subsequent invocations of the `rtems_rate_monotonic_period` directive will result in the task blocking for the remainder of the 100 tick period. If, for any reason, the body of the loop takes more than 100 ticks to execute, the `rtems_rate_monotonic_period` directive will return the `RTEMS_TIMEOUT` status. If the above task misses its deadline, it will delete the rate monotonic period and itself.

19.3.8 Task with Multiple Periods

This example consists of a single periodic task which, after initialization, performs two sets of actions every 100 clock ticks. The first set of actions is performed in the first forty clock

ticks of every 100 clock ticks, while the second set of actions is performed between the fortieth and seventieth clock ticks. The last thirty clock ticks are not used by this task.

```

rtems_task Periodic_task(rtems_task_argument arg)
{
    rtems_name      name_1, name_2;
    rtems_id        period_1, period_2;
    rtems_status_code status;

    name_1 = rtems_build_name( 'P', 'E', 'R', '1' );
    name_2 = rtems_build_name( 'P', 'E', 'R', '2' );

    (void ) rtems_rate_monotonic_create( name_1, &period_1 );
    (void ) rtems_rate_monotonic_create( name_2, &period_2 );

    while ( 1 ) {
        if ( rtems_rate_monotonic_period( period_1, 100 ) == TIMEOUT )
            break;

        if ( rtems_rate_monotonic_period( period_2, 40 ) == TIMEOUT )
            break;

        /*
         * Perform first set of actions between clock
         * ticks 0 and 39 of every 100 ticks.
         */

        if ( rtems_rate_monotonic_period( period_2, 30 ) == TIMEOUT )
            break;

        /*
         * Perform second set of actions between clock 40 and 69
         * of every 100 ticks. THEN ...
         *
         * Check to make sure we didn't miss the period_2 period.
         */

        if ( rtems_rate_monotonic_period( period_2, STATUS ) == TIMEOUT )
            break;

        (void) rtems_rate_monotonic_cancel( period_2 );
    }

    /* missed period so delete period and SELF */

    (void ) rtems_rate_monotonic_delete( period_1 );
    (void ) rtems_rate_monotonic_delete( period_2 );
    (void ) task_delete( SELF );
}

```

The above task creates two rate monotonic periods as part of its initialization. The first time the loop is executed, the `rtems_rate_monotonic_period` directive will initiate the `period_1` period for 100 ticks and return immediately. Subsequent invocations of the `rtems_rate_monotonic_period` directive for `period_1` will result in the task blocking for the remainder of the 100 tick period. The `period_2` period is used to control the execution time of the two sets of actions within each 100 tick period established by `period_1`. The `rtems_rate_monotonic_cancel(period_2)` call is performed to ensure that the `period_2` period does not expire while the task is blocked on the `period_1` period. If this cancel operation were not performed, every time the `rtems_rate_monotonic_period(period_2, 40)` call is executed, except for the initial one, a directive status of `RTEMS_TIMEOUT` is returned. It is important to note that every time this call is made, the `period_2` period will be initiated immediately and the task will not block.

If, for any reason, the task misses any deadline, the `rtems_rate_monotonic_period` directive will return the `RTEMS_TIMEOUT` directive status. If the above task misses its deadline, it will delete the rate monotonic periods and itself.

19.4 Directives

This section details the rate monotonic manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

19.4.1 RATE_MONOTONIC_CREATE - Create a rate monotonic period

CALLING SEQUENCE:

```
rtems_status_code rtems_rate_monotonic_create(  
    rtems_name  name,  
    rtems_id    *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - rate monotonic period created successfully

RTEMS_INVALID_NAME - invalid period name

RTEMS_TOO_MANY - too many periods created

DESCRIPTION:

This directive creates a rate monotonic period. The assigned rate monotonic id is returned in id. This id is used to access the period with other rate monotonic manager directives. For control and maintenance of the rate monotonic period, RTEMS allocates a PCB from the local PCB free pool and initializes it.

NOTES:

This directive will not cause the calling task to be preempted.

19.4.2 RATE_MONOTONIC_IDENT - Get ID of a period

CALLING SEQUENCE:

```
rtems_status_code rtems_rate_monotonic_ident(  
    rtems_name  name,  
    rtems_id    *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - period identified successfully

RTEMS_INVALID_NAME - period name not found

DESCRIPTION:

This directive obtains the period id associated with the period name to be acquired. If the period name is not unique, then the period id will match one of the periods with that name. However, this period id is not guaranteed to correspond to the desired period. The period id is used to access this period in other rate monotonic manager directives.

NOTES:

This directive will not cause the running task to be preempted.

19.4.3 RATE_MONOTONIC_CANCEL - Cancel a period

CALLING SEQUENCE:

```
    rtems_status_code rtems_rate_monotonic_cancel(  
        rtems_id id  
    );
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - period canceled successfully

RTEMS_INVALID_ID - invalid rate monotonic period id

RTEMS_NOT_OWNER_OF_RESOURCE - rate monotonic period not created by calling task

DESCRIPTION:

This directive cancels the rate monotonic period id. This period will be reinitiated by the next invocation of `rtems_rate_monotonic_period` with id.

NOTES:

This directive will not cause the running task to be preempted.

The rate monotonic period specified by id must have been created by the calling task.

19.4.4 RATE_MONOTONIC_DELETE - Delete a rate monotonic period

CALLING SEQUENCE:

```
rtcms_status_code rtcms_rate_monotonic_delete(  
    rtcms_id id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - period deleted successfully

RTEMS_INVALID_ID - invalid rate monotonic period id

DESCRIPTION:

This directive deletes the rate monotonic period specified by id. If the period is running, it is automatically canceled. The PCB for the deleted period is reclaimed by RTEMS.

NOTES:

This directive will not cause the running task to be preempted.

A rate monotonic period can be deleted by a task other than the task which created the period.

19.4.5 RATE_MONOTONIC_PERIOD - Conclude current/Start next period

CALLING SEQUENCE:

```
rtems_status_code rtems_rate_monotonic_period(  
    rtems_id      id,  
    rtems_interval length  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - period initiated successfully

RTEMS_INVALID_ID - invalid rate monotonic period id

RTEMS_NOT_OWNER_OF_RESOURCE - period not created by calling task

RTEMS_NOT_DEFINED - period has never been initiated (only possible when period is set to PERIOD_STATUS)

RTEMS_TIMEOUT - period has expired

DESCRIPTION:

This directive initiates the rate monotonic period id with a length of period ticks. If id is running, then the calling task will block for the remainder of the period before reinitiating the period with the specified period. If id was not running (either expired or never initiated), the period is immediately initiated and the directive returns immediately.

If invoked with a period of RTEMS_PERIOD_STATUS ticks, the current state of id will be returned. The directive status indicates the current state of the period. This does not alter the state or period of the period.

NOTES:

This directive will not cause the running task to be preempted.

19.4.6 RATE_MONOTONIC_GET_STATUS - Obtain status from a period

CALLING SEQUENCE:

```

rtems_status_code rtems_rate_monotonic_get_status(
    rtems_id          id,
    rtems_rate_monotonic_period_status *status
);

```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - period initiated successfully

RTEMS_INVALID_ID - invalid rate monotonic period id

RTEMS_INVALID_ADDRESS - invalid address of status

DESCRIPTION:

This directive returns status information associated with the rate monotonic period id in the following data structure:

```

typedef struct {
    rtems_id          owner;
    rtems_rate_monotonic_period_status state;
    rtems_rate_monotonic_period_time_t since_last_period;
    rtems_thread_cpu_usage_t          executed_since_last_period;
} rtems_rate_monotonic_period_status;

```

A configure time option can be used to select whether the time information is given in ticks or seconds and nanoseconds. The default is seconds and nanoseconds. If the period's state is `RATE_MONOTONIC_INACTIVE`, both time values will be set to 0. Otherwise, both time values will contain time information since the last invocation of the `rtems_rate_monotonic_period` directive. More specifically, the (ticks_)since_last_period value contains the elapsed time which has occurred since the last invocation of the `rtems_rate_monotonic_period` directive and the (ticks_)executed_since_last_period contains how much processor time the owning task has consumed since the invocation of the `rtems_rate_monotonic_period` directive.

NOTES:

This directive will not cause the running task to be preempted.

19.4.7 RATE_MONOTONIC_GET_STATISTICS - Obtain statistics from a period

CALLING SEQUENCE:

```

rtems_status_code rtems_rate_monotonic_get_statistics(
    rtems_id          id,
    rtems_rate_monotonic_period_statistics *statistics
);

```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - period initiated successfully
 RTEMS_INVALID_ID - invalid rate monotonic period id
 RTEMS_INVALID_ADDRESS - invalid address of statistics

DESCRIPTION:

This directive returns statistics information associated with the rate monotonic period id in the following data structure:

```

typedef struct {
    uint32_t      count;
    uint32_t      missed_count;
#ifdef RTEMS_ENABLE_NANOSECOND_CPU_USAGE_STATISTICS
    struct timespec min_cpu_time;
    struct timespec max_cpu_time;
    struct timespec total_cpu_time;
#else
    uint32_t      min_cpu_time;
    uint32_t      max_cpu_time;
    uint32_t      total_cpu_time;
#endif
#ifdef RTEMS_ENABLE_NANOSECOND_RATE_MONOTONIC_STATISTICS
    struct timespec min_wall_time;
    struct timespec max_wall_time;
    struct timespec total_wall_time;
#else
    uint32_t      min_wall_time;
    uint32_t      max_wall_time;
    uint32_t      total_wall_time;
#endif
} rtems_rate_monotonic_period_statistics;

```

This directive returns the current statistics information for the period instance associated with id. The information returned is indicated by the structure above.

NOTES:

This directive will not cause the running task to be preempted.

19.4.8 RATE_MONOTONIC_RESET_STATISTICS - Reset statistics for a period

CALLING SEQUENCE:

```
    rtems_status_code rtems_rate_monotonic_reset_statistics(  
        rtems_id id  
    );
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - period initiated successfully

RTEMS_INVALID_ID - invalid rate monotonic period id

DESCRIPTION:

This directive resets the statistics information associated with this rate monotonic period instance.

NOTES:

This directive will not cause the running task to be preempted.

19.4.9 RATE_MONOTONIC_RESET_ALL_STATISTICS - Reset statistics for all periods

CALLING SEQUENCE:

```
void rtems_rate_monotonic_reset_all_statistics(void);
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive resets the statistics information associated with all rate monotonic period instances.

NOTES:

This directive will not cause the running task to be preempted.

19.4.10 RATE_MONOTONIC_REPORT_STATISTICS - Print period statistics report

CALLING SEQUENCE:

```
void rtems_rate_monotonic_report_statistics(void);
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive prints a report on all active periods which have executed at least one period. The following is an example of the output generated by this directive.

ID	OWNER	PERIODS	MISSED	CPU TIME MIN/MAX/AVG	WALL TIME MIN/MAX/AVG
0x42010001	TA1	502	0	0/1/0.99	0/0/0.00
0x42010002	TA2	502	0	0/1/0.99	0/0/0.00
0x42010003	TA3	501	0	0/1/0.99	0/0/0.00
0x42010004	TA4	501	0	0/1/0.99	0/0/0.00
0x42010005	TA5	10	0	0/1/0.90	0/0/0.00

NOTES:

This directive will not cause the running task to be preempted.

20 Barrier Manager

20.1 Introduction

The barrier manager provides a unique synchronization capability which can be used to have a set of tasks block and be unblocked as a set. The directives provided by the barrier manager are:

- `rtems_barrier_create` - Create a barrier
- `rtems_barrier_ident` - Get ID of a barrier
- `rtems_barrier_delete` - Delete a barrier
- `rtems_barrier_wait` - Wait at a barrier
- `rtems_barrier_release` - Release a barrier

20.2 Background

A barrier can be viewed as a gate at which tasks wait until the gate is opened. This has many analogies in the real world. Horses and other farm animals may approach a closed gate and gather in front of it, waiting for someone to open the gate so they may proceed. Similarly, cticket holders gather at the gates of arenas before concerts or sporting events waiting for the arena personnel to open the gates so they may enter.

Barriers are useful during application initialization. Each application task can perform its local initialization before waiting for the application as a whole to be initialized. Once all tasks have completed their independent initializations, the "application ready" barrier can be released.

20.2.1 Automatic Versus Manual Barriers

Just as with a real-world gate, barriers may be configured to be manually opened or automatically opened. All tasks calling the `rtems_barrier_wait` directive will block until a controlling task invokes the `rtems_barrier_release` directive.

Automatic barriers are created with a limit to the number of tasks which may simultaneously block at the barrier. Once this limit is reached, all of the tasks are released. For example, if the automatic limit is ten tasks, then the first nine tasks calling the `rtems_barrier_wait` directive will block. When the tenth task calls the `rtems_barrier_wait` directive, the nine blocked tasks will be released and the tenth task returns to the caller without blocking.

20.2.2 Building a Barrier Attribute Set

In general, an attribute set is built by a bitwise OR of the desired attribute components. The following table lists the set of valid barrier attributes:

- `RTEMS_BARRIER_AUTOMATIC_RELEASE` - automatically release the barrier when the configured number of tasks are blocked
- `RTEMS_BARRIER_MANUAL_RELEASE` - only release the barrier when the application invokes the `rtems_barrier_release` directive. (default)

NOTE: Barriers only support FIFO blocking order because all waiting tasks are released as a set. Thus the released tasks will all become ready to execute at the same time and compete for the processor based upon their priority.

Attribute values are specifically designed to be mutually exclusive, therefore bitwise OR and addition operations are equivalent as long as each attribute appears exactly once in the component list. An attribute listed as a default is not required to appear in the attribute list, although it is a good programming practice to specify default attributes. If all defaults are desired, the attribute `RTEMS_DEFAULT_ATTRIBUTES` should be specified on this call.

This example demonstrates the `attribute_set` parameter needed to create a barrier with the automatic release policy. The `attribute_set` parameter passed to the `rtems_barrier_create` directive will be `RTEMS_BARRIER_AUTOMATIC_RELEASE`. In this case, the user must also specify the *maximum_waiters* parameter.

20.3 Operations

20.3.1 Creating a Barrier

The `rtems_barrier_create` directive creates a barrier with a user-specified name and the desired attributes. RTEMS allocates a Barrier Control Block (BCB) from the BCB free list. This data structure is used by RTEMS to manage the newly created barrier. Also, a unique barrier ID is generated and returned to the calling task.

20.3.2 Obtaining Barrier IDs

When a barrier is created, RTEMS generates a unique barrier ID and assigns it to the created barrier until it is deleted. The barrier ID may be obtained by either of two methods. First, as the result of an invocation of the `rtems_barrier_create` directive, the barrier ID is stored in a user provided location. Second, the barrier ID may be obtained later using the `rtems_barrier_ident` directive. The barrier ID is used by other barrier manager directives to access this barrier.

20.3.3 Waiting at a Barrier

The `rtems_barrier_wait` directive is used to wait at the specified barrier. Since a barrier is, by definition, never immediately, the task may wait forever for the barrier to be released or it may specify a timeout. Specifying a timeout limits the interval the task will wait before returning with an error status code.

If the barrier is configured as automatic and there are already one less than the maximum number of waiters, then the call will unblock all tasks waiting at the barrier and the caller will return immediately.

When the task does wait to acquire the barrier, then it is placed in the barrier's task wait queue in FIFO order. All tasks waiting on a barrier are returned an error code when the barrier is deleted.

20.3.4 Releasing a Barrier

The `rtems_barrier_release` directive is used to release the specified barrier. When the `rtems_barrier_release` is invoked, all tasks waiting at the barrier are immediately made ready to execute and begin to compete for the processor to execute.

20.3.5 Deleting a Barrier

The `rtems_barrier_delete` directive removes a barrier from the system and frees its control block. A barrier can be deleted by any local task that knows the barrier's ID. As a result of this directive, all tasks blocked waiting for the barrier to be released, will be readied and returned a status code which indicates that the barrier was deleted. Any subsequent references to the barrier's name and ID are invalid.

20.4 Directives

This section details the barrier manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

20.4.1 BARRIER_CREATE - Create a barrier

CALLING SEQUENCE:

```

rtems_status_code rtems_barrier_create(
    rtems_name      name,
    rtems_attribute attribute_set,
    uint32_t        maximum_waiters,
    rtems_id        *id
);

```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - barrier created successfully

RTEMS_INVALID_NAME - invalid barrier name

RTEMS_INVALID_ADDRESS - id is NULL

RTEMS_TOO_MANY - too many barriers created

DESCRIPTION:

This directive creates a barrier which resides on the local node. The created barrier has the user-defined name specified in `name` and the initial count specified in `count`. For control and maintenance of the barrier, RTEMS allocates and initializes a BCB. The RTEMS-assigned barrier id is returned in `id`. This barrier id is used with other barrier related directives to access the barrier.

RTEMS_BARRIER_MANUAL_RELEASE - only release

Specifying RTEMS_BARRIER_AUTOMATIC_RELEASE in `attribute_set` causes tasks calling the `rtems_barrier_wait` directive to block until there are `maximum_waiters - 1` tasks waiting at the barrier. When the `maximum_waiters` task invokes the `rtems_barrier_wait` directive, the previous `maximum_waiters - 1` tasks are automatically released and the caller returns.

In contrast, when the RTEMS_BARRIER_MANUAL_RELEASE attribute is specified, there is no limit on the number of tasks that will block at the barrier. Only when the `rtems_barrier_release` directive is invoked, are the tasks waiting at the barrier unblocked.

NOTES:

This directive will not cause the calling task to be preempted.

The following barrier attribute constants are defined by RTEMS:

- RTEMS_BARRIER_AUTOMATIC_RELEASE - automatically release the barrier when the configured number of tasks are blocked
- RTEMS_BARRIER_MANUAL_RELEASE - only release the barrier when the application invokes the `rtems_barrier_release` directive. (default)

20.4.2 BARRIER_IDENT - Get ID of a barrier

CALLING SEQUENCE:

```
rtems_status_code rtems_barrier_ident(  
    rtems_name      name,  
    rtems_id        *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - barrier identified successfully

RTEMS_INVALID_NAME - barrier name not found

RTEMS_INVALID_NODE - invalid node id

DESCRIPTION:

This directive obtains the barrier id associated with the barrier name. If the barrier name is not unique, then the barrier id will match one of the barriers with that name. However, this barrier id is not guaranteed to correspond to the desired barrier. The barrier id is used by other barrier related directives to access the barrier.

NOTES:

This directive will not cause the running task to be preempted.

20.4.3 BARRIER_DELETE - Delete a barrier

CALLING SEQUENCE:

```
    rtems_status_code rtems_barrier_delete(  
        rtems_id id  
    );
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - barrier deleted successfully

RTEMS_INVALID_ID - invalid barrier id

DESCRIPTION:

This directive deletes the barrier specified by `id`. All tasks blocked waiting for the barrier to be released will be readied and returned a status code which indicates that the barrier was deleted. The BCB for this barrier is reclaimed by RTEMS.

NOTES:

The calling task will be preempted if it is enabled by the task's execution mode and a higher priority local task is waiting on the deleted barrier. The calling task will NOT be preempted if all of the tasks that are waiting on the barrier are remote tasks.

The calling task does not have to be the task that created the barrier. Any local task that knows the barrier id can delete the barrier.

20.4.4 BARRIER_OBTAIN - Acquire a barrier

CALLING SEQUENCE:

```
rtcms_status_code rtcms_barrier_wait(  
    rtcms_id      id,  
    rtcms_interval timeout  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - barrier obtained successfully

RTEMS_UNSATISFIED - barrier not available

RTEMS_TIMEOUT - timed out waiting for barrier

RTEMS_OBJECT_WAS_DELETED - barrier deleted while waiting

RTEMS_INVALID_ID - invalid barrier id

DESCRIPTION:

This directive acquires the barrier specified by id. The RTEMS_WAIT and RTEMS_NO_WAIT components of the options parameter indicate whether the calling task wants to wait for the barrier to become available or return immediately if the barrier is not currently available. With either RTEMS_WAIT or RTEMS_NO_WAIT, if the current barrier count is positive, then it is decremented by one and the barrier is successfully acquired by returning immediately with a successful return code.

Conceptually, the calling task should always be thought of as blocking when it makes this call and being unblocked when the barrier is released. If the barrier is configured for manual release, this rule of thumb will always be valid. If the barrier is configured for automatic release, all callers will block except for the one which is the Nth task which trips the automatic release condition.

The timeout parameter specifies the maximum interval the calling task is willing to be blocked waiting for the barrier. If it is set to RTEMS_NO_TIMEOUT, then the calling task will wait forever. If the barrier is available or the RTEMS_NO_WAIT option component is set, then timeout is ignored.

NOTES:

The following barrier acquisition option constants are defined by RTEMS:

- RTEMS_WAIT - task will wait for barrier (default)
- RTEMS_NO_WAIT - task should not wait

A clock tick is required to support the timeout functionality of this directive.

20.4.5 BARRIER_RELEASE - Release a barrier

CALLING SEQUENCE:

```
rtems_status_code rtems_barrier_release(  
    rtems_id id,  
    uint32_t *released  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - barrier released successfully

RTEMS_INVALID_ID - invalid barrier id

DESCRIPTION:

This directive releases the barrier specified by id. All tasks waiting at the barrier will be unblocked. If the running task's preemption mode is enabled and one of the unblocked tasks has a higher priority than the running task.

NOTES:

The calling task may be preempted if it causes a higher priority task to be made ready for execution.

21 Board Support Packages

21.1 Introduction

A board support package (BSP) is a collection of user-provided facilities which interface RTEMS and an application with a specific hardware platform. These facilities may include hardware initialization, device drivers, user extensions, and a Multiprocessor Communications Interface (MPCI). However, a minimal BSP need only support processor reset and initialization and, if needed, a clock tick.

21.2 Reset and Initialization

An RTEMS based application is initiated or re-initiated when the processor is reset. This initialization code is responsible for preparing the target platform for the RTEMS application. Although the exact actions performed by the initialization code are highly processor and target dependent, the logical functionality of these actions are similar across a variety of processors and target platforms.

Normally, the BSP and some of the application initialization is intertwined in the RTEMS initialization sequence controlled by the shared function `boot_card()`.

The reset application initialization code is executed first when the processor is reset. All of the hardware must be initialized to a quiescent state by this software before initializing RTEMS. When in quiescent state, devices do not generate any interrupts or require any servicing by the application. Some of the hardware components may be initialized in this code as well as any application initialization that does not involve calls to RTEMS directives.

The processor's Interrupt Vector Table which will be used by the application may need to be set to the required value by the reset application initialization code. Because interrupts are enabled automatically by RTEMS as part of the context switch to the first task, the Interrupt Vector Table MUST be set before this directive is invoked to ensure correct interrupt vectoring. The processor's Interrupt Vector Table must be accessible by RTEMS as it will be modified by the when installing user Interrupt Service Routines (ISRs) On some CPUs, RTEMS installs it's own Interrupt Vector Table as part of initialization and thus these requirements are met automatically. The reset code which is executed before the call to any RTEMS initialization routines has the following requirements:

- Must not make any blocking RTEMS directive calls.
- If the processor supports multiple privilege levels, must leave the processor in the most privileged, or supervisory, state.
- Must allocate a stack of sufficient size to execute the initialization and shutdown of the system. This stack area will NOT be used by any task once the system is initialized. This stack is often reserved via the linker script or in the assembly language start up file.
- Must initialize the stack pointer for the initialization process to that allocated.
- Must initialize the processor's Interrupt Vector Table.
- Must disable all maskable interrupts.

- If the processor supports a separate interrupt stack, must allocate the interrupt stack and initialize the interrupt stack pointer.

At the end of the initialization sequence, RTEMS does not return to the BSP initialization code, but instead context switches to the highest priority task to begin application execution. This task is typically a User Initialization Task which is responsible for performing both local and global application initialization which is dependent on RTEMS facilities. It is also responsible for initializing any higher level RTEMS services the application uses such as networking and blocking device drivers.

21.2.1 Interrupt Stack Requirements

The worst-case stack usage by interrupt service routines must be taken into account when designing an application. If the processor supports interrupt nesting, the stack usage must include the deepest nest level. The worst-case stack usage must account for the following requirements:

- Processor's interrupt stack frame
- Processor's subroutine call stack frame
- RTEMS system calls
- Registers saved on stack
- Application subroutine calls

The size of the interrupt stack must be greater than or equal to the configured minimum stack size.

21.2.2 Processors with a Separate Interrupt Stack

Some processors support a separate stack for interrupts. When an interrupt is vectored and the interrupt is not nested, the processor will automatically switch from the current stack to the interrupt stack. The size of this stack is based solely on the worst-case stack usage by interrupt service routines.

The dedicated interrupt stack for the entire application on some architectures is supplied and initialized by the reset and initialization code of the user's Board Support Package. Whether allocated and initialized by the BSP or RTEMS, since all ISRs use this stack, the stack size must take into account the worst case stack usage by any combination of nested ISRs.

21.2.3 Processors Without a Separate Interrupt Stack

Some processors do not support a separate stack for interrupts. In this case, without special assistance every task's stack must include enough space to handle the task's worst-case stack usage as well as the worst-case interrupt stack usage. This is necessary because the worst-case interrupt nesting could occur while any task is executing.

On many processors without dedicated hardware managed interrupt stacks, RTEMS manages a dedicated interrupt stack in software. If this capability is supported on a CPU, then it is logically equivalent to the processor supporting a separate interrupt stack in hardware.

21.3 Device Drivers

Device drivers consist of control software for special peripheral devices and provide a logical interface for the application developer. The RTEMS I/O manager provides directives which allow applications to access these device drivers in a consistent fashion. A Board Support Package may include device drivers to access the hardware on the target platform. These devices typically include serial and parallel ports, counter/timer peripherals, real-time clocks, disk interfaces, and network controllers.

For more information on device drivers, refer to the I/O Manager chapter.

21.3.1 Clock Tick Device Driver

Most RTEMS applications will include a clock tick device driver which invokes the `rtems_clock_tick` directive at regular intervals. The clock tick is necessary if the application is to utilize timeslicing, the clock manager, the timer manager, the rate monotonic manager, or the timeout option on blocking directives.

The clock tick is usually provided as an interrupt from a counter/timer or a real-time clock device. When a counter/timer is used to provide the clock tick, the device is typically programmed to operate in continuous mode. This mode selection causes the device to automatically reload the initial count and continue the countdown without programmer intervention. This reduces the overhead required to manipulate the counter/timer in the clock tick ISR and increases the accuracy of tick occurrences. The initial count can be based on the `microseconds_per_tick` field in the RTEMS Configuration Table. An alternate approach is to set the initial count for a fixed time period (such as one millisecond) and have the ISR invoke `rtems_clock_tick` on the configured `microseconds_per_tick` boundaries. Obviously, this can induce some error if the configured `microseconds_per_tick` is not evenly divisible by the chosen clock interrupt quantum.

It is important to note that the interval between clock ticks directly impacts the granularity of RTEMS timing operations. In addition, the frequency of clock ticks is an important factor in the overall level of system overhead. A high clock tick frequency results in less processor time being available for task execution due to the increased number of clock tick ISRs.

21.4 User Extensions

RTEMS allows the application developer to augment selected features by invoking user-supplied extension routines when the following system events occur:

- Task creation
- Task initiation
- Task reinitiation
- Task deletion
- Task context switch
- Post task context switch
- Task begin
- Task exits
- Fatal error detection

User extensions can be used to implement a wide variety of functions including execution profiling, non-standard coprocessor support, debug support, and error detection and recovery. For example, the context of a non-standard numeric coprocessor may be maintained via the user extensions. In this example, the task creation and deletion extensions are responsible for allocating and deallocating the context area, the task initiation and reinitiation extensions would be responsible for priming the context area, and the task context switch extension would save and restore the context of the device.

For more information on user extensions, refer to the [Chapter 22 \[User Extensions Manager\]](#), [page 233](#) chapter.

21.5 Multiprocessor Communications Interface (MPCI)

RTEMS requires that an MPCI layer be provided when a multiple node application is developed. This MPCI layer must provide an efficient and reliable communications mechanism between the multiple nodes. Tasks on different nodes communicate and synchronize with one another via the MPCI. Each MPCI layer must be tailored to support the architecture of the target platform.

For more information on the MPCI, refer to the Multiprocessing Manager chapter.

21.5.1 Tightly-Coupled Systems

A tightly-coupled system is a multiprocessor configuration in which the processors communicate solely via shared global memory. The MPCI can simply place the RTEMS packets in the shared memory space. The two primary considerations when designing an MPCI for a tightly-coupled system are data consistency and informing another node of a packet.

The data consistency problem may be solved using atomic "test and set" operations to provide a "lock" in the shared memory. It is important to minimize the length of time any particular processor locks a shared data structure.

The problem of informing another node of a packet can be addressed using one of two techniques. The first technique is to use an interprocessor interrupt capability to cause an interrupt on the receiving node. This technique requires that special support hardware be provided by either the processor itself or the target platform. The second technique is to have a node poll for arrival of packets. The drawback to this technique is the overhead associated with polling.

21.5.2 Loosely-Coupled Systems

A loosely-coupled system is a multiprocessor configuration in which the processors communicate via some type of communications link which is not shared global memory. The MPCI sends the RTEMS packets across the communications link to the destination node. The characteristics of the communications link vary widely and have a significant impact on the MPCI layer. For example, the bandwidth of the communications link has an obvious impact on the maximum MPCI throughput.

The characteristics of a shared network, such as Ethernet, lend themselves to supporting an MPCI layer. These networks provide both the point-to-point and broadcast capabilities which are expected by RTEMS.

21.5.3 Systems with Mixed Coupling

A mixed-coupling system is a multiprocessor configuration in which the processors communicate via both shared memory and communications links. A unique characteristic of mixed-coupling systems is that a node may not have access to all communication methods. There may be multiple shared memory areas and communication links. Therefore, one of the primary functions of the MPCI layer is to efficiently route RTEMS packets between nodes. This routing may be based on numerous algorithms. In addition, the router may provide alternate communications paths in the event of an overload or a partial failure.

21.5.4 Heterogeneous Systems

Designing an MPCI layer for a heterogeneous system requires special considerations by the developer. RTEMS is designed to eliminate many of the problems associated with sharing data in a heterogeneous environment. The MPCI layer need only address the representation of thirty-two (32) bit unsigned quantities.

For more information on supporting a heterogeneous system, refer the Supporting Heterogeneous Environments in the Multiprocessing Manager chapter.

22 User Extensions Manager

22.1 Introduction

The RTEMS User Extensions Manager allows the application developer to augment the executive by allowing them to supply extension routines which are invoked at critical system events. The directives provided by the user extensions manager are:

- `rtems_extension_create` - Create an extension set
- `rtems_extension_ident` - Get ID of an extension set
- `rtems_extension_delete` - Delete an extension set

22.2 Background

User extension routines are invoked when the following system events occur:

- Task creation
- Task initiation
- Task reinitiation
- Task deletion
- Task context switch
- Post task context switch
- Task begin
- Task exits
- Fatal error detection

These extensions are invoked as a function with arguments that are appropriate to the system event.

22.2.1 Extension Sets

An extension set is defined as a set of routines which are invoked at each of the critical system events at which user extension routines are invoked. Together a set of these routines typically perform a specific functionality such as performance monitoring or debugger support. RTEMS is informed of the entry points which constitute an extension set via the following structure:

```
typedef struct {
    rtems_task_create_extension    thread_create;
    rtems_task_start_extension    thread_start;
    rtems_task_restart_extension  thread_restart;
    rtems_task_delete_extension   thread_delete;
    rtems_task_switch_extension   thread_switch;
    rtems_task_begin_extension    thread_begin;
    rtems_task_exitted_extension  thread_exitted;
    rtems_fatal_extension         fatal;
} rtems_extensions_table;
```

RTEMS allows the user to have multiple extension sets active at the same time. First, a single static extension set may be defined as the application's User Extension Table which is included as part of the Configuration Table. This extension set is active for the entire life of the system and may not be deleted. This extension set is especially important because it is the only way the application can provide a FATAL error extension which is invoked if RTEMS fails during the `initialize_executive` directive. The static extension set is optional and may be configured as NULL if no static extension set is required.

Second, the user can install dynamic extensions using the `rtems_extension_create` directive. These extensions are RTEMS objects in that they have a name, an ID, and can be dynamically created and deleted. In contrast to the static extension set, these extensions can only be created and installed after the `initialize_executive` directive successfully completes execution. Dynamic extensions are useful for encapsulating the functionality of an extension set. For example, the application could use extensions to manage a special coprocessor, do performance monitoring, and to do stack bounds checking. Each of these extension sets could be written and installed independently of the others.

All user extensions are optional and RTEMS places no naming restrictions on the user. The user extension entry points are copied into an internal RTEMS structure. This means the user does not need to keep the table after creating it, and changing the handler entry points dynamically in a table once created has no effect. Creating a table local to a function can save space in space limited applications.

Extension switches do not effect the context switch overhead if no switch handler is installed.

22.2.2 TCB Extension Area

RTEMS provides for a pointer to a user-defined data area for each extension set to be linked to each task's control block. This set of pointers is an extension of the TCB and can be used to store additional data required by the user's extension functions. It is also possible for a user extension to utilize the notepad locations associated with each task although this may conflict with application usage of those particular notepads.

The TCB extension is an array of pointers in the TCB. The index into the table can be obtained from the extension id returned when the extension is created:

```
index = rtems_object_id_get_index(extension_id);
```

The number of pointers in the area is the same as the number of user extension sets configured. This allows an application to augment the TCB with user-defined information. For example, an application could implement task profiling by storing timing statistics in the TCB's extended memory area. When a task context switch is being executed, the `TASK_SWITCH` extension could read a real-time clock to calculate how long the task being swapped out has run as well as timestamp the starting time for the task being swapped in.

If used, the extended memory area for the TCB should be allocated and the TCB extension pointer should be set at the time the task is created or started by either the `TASK_CREATE` or `TASK_START` extension. The application is responsible for managing this extended memory area for the TCBs. The memory may be reinitialized by the `TASK_RESTART` extension and should be deallocated by the `TASK_DELETE` extension when the task is

deleted. Since the TCB extension buffers would most likely be of a fixed size, the RTEMS partition manager could be used to manage the application's extended memory area. The application could create a partition of fixed size TCB extension buffers and use the partition manager's allocation and deallocation directives to obtain and release the extension buffers.

22.2.3 Extensions

The sections that follow will contain a description of each extension. Each section will contain a prototype of a function with the appropriate calling sequence for the corresponding extension. The names given for the C function and its arguments are all defined by the user. The names used in the examples were arbitrarily chosen and impose no naming conventions on the user.

22.2.3.1 TASK_CREATE Extension

The TASK_CREATE extension directly corresponds to the `rtems_task_create` directive. If this extension is defined in any static or dynamic extension set and a task is being created, then the extension routine will automatically be invoked by RTEMS. The extension should have a prototype similar to the following:

```
bool user_task_create(  
    rtems_tcb *current_task,  
    rtems_tcb *new_task  
);
```

where `current_task` can be used to access the TCB for the currently executing task, and `new_task` can be used to access the TCB for the new task being created. This extension is invoked from the `rtems_task_create` directive after `new_task` has been completely initialized, but before it is placed on a ready TCB chain.

The user extension is expected to return the boolean value `true` if it successfully executed and `false` otherwise. A task create user extension will frequently attempt to allocate resources. If this allocation fails, then the extension should return `false` and the entire task create operation will fail.

22.2.3.2 TASK_START Extension

The TASK_START extension directly corresponds to the `task_start` directive. If this extension is defined in any static or dynamic extension set and a task is being started, then the extension routine will automatically be invoked by RTEMS. The extension should have a prototype similar to the following:

```
void user_task_start(  
    rtems_tcb *current_task,  
    rtems_tcb *started_task  
);
```

where `current_task` can be used to access the TCB for the currently executing task, and `started_task` can be used to access the TCB for the dormant task being started. This extension is invoked from the `task_start` directive after `started_task` has been made ready to start execution, but before it is placed on a ready TCB chain.

22.2.3.3 TASK_RESTART Extension

The TASK_RESTART extension directly corresponds to the task_restart directive. If this extension is defined in any static or dynamic extension set and a task is being restarted, then the extension should have a prototype similar to the following:

```
void user_task_restart(  
    rtems_tcb *current_task,  
    rtems_tcb *restarted_task  
);
```

where current_task can be used to access the TCB for the currently executing task, and restarted_task can be used to access the TCB for the task being restarted. This extension is invoked from the task_restart directive after restarted_task has been made ready to start execution, but before it is placed on a ready TCB chain.

22.2.3.4 TASK_DELETE Extension

The TASK_DELETE extension is associated with the task_delete directive. If this extension is defined in any static or dynamic extension set and a task is being deleted, then the extension routine will automatically be invoked by RTEMS. The extension should have a prototype similar to the following:

```
void user_task_delete(  
    rtems_tcb *current_task,  
    rtems_tcb *deleted_task  
);
```

where current_task can be used to access the TCB for the currently executing task, and deleted_task can be used to access the TCB for the task being deleted. This extension is invoked from the task_delete directive after the TCB has been removed from a ready TCB chain, but before all its resources including the TCB have been returned to their respective free pools. This extension should not call any RTEMS directives if a task is deleting itself (current_task is equal to deleted_task).

22.2.3.5 TASK_SWITCH Extension

The TASK_SWITCH extension corresponds to a task context switch. If this extension is defined in any static or dynamic extension set and a task context switch is in progress, then the extension routine will automatically be invoked by RTEMS. The extension should have a prototype similar to the following:

```
void user_task_switch(  
    rtems_tcb *current_task,  
    rtems_tcb *heir_task  
);
```

where current_task can be used to access the TCB for the task that is being swapped out, and heir_task can be used to access the TCB for the task being swapped in. This extension is invoked from RTEMS' dispatcher routine after the current_task context has been saved, but before the heir_task context has been restored. This extension should not call any RTEMS directives.

22.2.3.6 TASK_BEGIN Extension

The TASK_BEGIN extension is invoked when a task begins execution. It is invoked immediately before the body of the starting procedure and executes in the context in the task. This user extension have a prototype similar to the following:

```
void user_task_begin(
    rtems_tcb *current_task
);
```

where `current_task` can be used to access the TCB for the currently executing task which has begun. The distinction between the TASK_BEGIN and TASK_START extension is that the TASK_BEGIN extension is executed in the context of the actual task while the TASK_START extension is executed in the context of the task performing the `task_start` directive. For most extensions, this is not a critical distinction.

22.2.3.7 TASK_EXITTED Extension

The TASK_EXITTED extension is invoked when a task exits the body of the starting procedure by either an implicit or explicit return statement. This user extension have a prototype similar to the following:

```
void user_task_exitted(
    rtems_tcb *current_task
);
```

where `current_task` can be used to access the TCB for the currently executing task which has just exited.

Although exiting of task is often considered to be a fatal error, this extension allows recovery by either restarting or deleting the exiting task. If the user does not wish to recover, then a fatal error may be reported. If the user does not provide a TASK_EXITTED extension or the provided handler returns control to RTEMS, then the RTEMS default handler will be used. This default handler invokes the directive `fatal_error_occurred` with the `RTEMS_TASK_EXITTED` directive status.

22.2.3.8 FATAL Error Extension

The FATAL error extension is associated with the `fatal_error_occurred` directive. If this extension is defined in any static or dynamic extension set and the `fatal_error_occurred` directive has been invoked, then this extension will be called. This extension should have a prototype similar to the following:

```
void user_fatal_error(
    Internal_errors_Source the_source,
    bool                  is_internal,
    uint32_t              the_error
);
```

where `the_error` is the error code passed to the `fatal_error_occurred` directive. This extension is invoked from the `fatal_error_occurred` directive.

If defined, the user's FATAL error extension is invoked before RTEMS' default fatal error routine is invoked and the processor is stopped. For example, this extension could be used

to pass control to a debugger when a fatal error occurs. This extension should not call any RTEMS directives.

22.2.4 Order of Invocation

When one of the critical system events occur, the user extensions are invoked in either "forward" or "reverse" order. Forward order indicates that the static extension set is invoked followed by the dynamic extension sets in the order in which they were created. Reverse order means that the dynamic extension sets are invoked in the opposite of the order in which they were created followed by the static extension set. By invoking the extension sets in this order, extensions can be built upon one another. At the following system events, the extensions are invoked in forward order:

- Task creation
- Task initiation
- Task reinitiation
- Task deletion
- Task context switch
- Post task context switch
- Task begins to execute

At the following system events, the extensions are invoked in reverse order:

- Task deletion
- Fatal error detection

At these system events, the extensions are invoked in reverse order to insure that if an extension set is built upon another, the more complicated extension is invoked before the extension set it is built upon. For example, by invoking the static extension set last it is known that the "system" fatal error extension will be the last fatal error extension executed. Another example is use of the task delete extension by the Standard C Library. Extension sets which are installed after the Standard C Library will operate correctly even if they utilize the C Library because the C Library's TASK_DELETE extension is invoked after that of the other extensions.

22.3 Operations

22.3.1 Creating an Extension Set

The `rtems_extension_create` directive creates and installs an extension set by allocating a Extension Set Control Block (ESCB), assigning the extension set a user-specified name, and assigning it an extension set ID. Newly created extension sets are immediately installed and are invoked upon the next system even supporting an extension.

22.3.2 Obtaining Extension Set IDs

When an extension set is created, RTEMS generates a unique extension set ID and assigns it to the created extension set until it is deleted. The extension ID may be obtained by either of two methods. First, as the result of an invocation of the `rtems_extension_create`

directive, the extension set ID is stored in a user provided location. Second, the extension set ID may be obtained later using the `rtems_extension_ident` directive. The extension set ID is used by other directives to manipulate this extension set.

22.3.3 Deleting an Extension Set

The `rtems_extension_delete` directive is used to delete an extension set. The extension set's control block is returned to the ESCB free list when it is deleted. An extension set can be deleted by a task other than the task which created the extension set. Any subsequent references to the extension's name and ID are invalid.

22.4 Directives

This section details the user extension manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

22.4.1 EXTENSION_CREATE - Create a extension set

CALLING SEQUENCE:

```
rtcms_status_code rtcms_extension_create(  
    rtcms_name          name,  
    rtcms_extensions_table *table,  
    rtcms_id            *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - extension set created successfully

RTEMS_INVALID_NAME - invalid extension set name

RTEMS_TOO_MANY - too many extension sets created

DESCRIPTION:

This directive creates a extension set. The assigned extension set id is returned in id. This id is used to access the extension set with other user extension manager directives. For control and maintenance of the extension set, RTEMS allocates an ESCB from the local ESCB free pool and initializes it.

NOTES:

This directive will not cause the calling task to be preempted.

22.4.2 EXTENSION_IDENT - Get ID of a extension set

CALLING SEQUENCE:

```
rtems_status_code rtems_extension_ident(  
    rtems_name  name,  
    rtems_id    *id  
);
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - extension set identified successfully

RTEMS_INVALID_NAME - extension set name not found

DESCRIPTION:

This directive obtains the extension set id associated with the extension set name to be acquired. If the extension set name is not unique, then the extension set id will match one of the extension sets with that name. However, this extension set id is not guaranteed to correspond to the desired extension set. The extension set id is used to access this extension set in other extension set related directives.

NOTES:

This directive will not cause the running task to be preempted.

22.4.3 EXTENSION_DELETE - Delete a extension set

CALLING SEQUENCE:

```
    rtems_status_code rtems_extension_delete(  
        rtems_id id  
    );
```

DIRECTIVE STATUS CODES:

RTEMS_SUCCESSFUL - extension set deleted successfully

RTEMS_INVALID_ID - invalid extension set id

DESCRIPTION:

This directive deletes the extension set specified by id. If the extension set is running, it is automatically canceled. The ESCB for the deleted extension set is reclaimed by RTEMS.

NOTES:

This directive will not cause the running task to be preempted.

A extension set can be deleted by a task other than the task which created the extension set.

NOTES:

This directive will not cause the running task to be preempted.

23 Configuring a System

23.1 Introduction

RTEMS must be configured for an application. This configuration information encompasses a variety of information including the length of each clock tick, the maximum number of each RTEMS object that can be created, the application initialization tasks, and the device drivers in the application. This information is placed in data structures that are given to RTEMS at system initialization time. This chapter details the format of these data structures as well as a simpler mechanism to automate the generation of these structures.

23.2 Automatic Generation of System Configuration

RTEMS provides the `rtems/confdefs.h` C language header file that based on the setting of a variety of macros can automatically produce nearly all of the configuration tables required by an RTEMS application. Rather than building the individual tables by hand, the application simply specifies the values for the configuration parameters it wishes to set. In the following example, the configuration information for a simple system with a message queue and a time slice of 50 milliseconds is configured:

```
#define CONFIGURE_APPLICATION_NEEDS_CONSOLE_DRIVER
#define CONFIGURE_APPLICATION_NEEDS_CLOCK_DRIVER

#define CONFIGURE_MICROSECONDS_PER_TICK    1000 /* 1 millisecond */
#define CONFIGURE_TICKS_PER_TIMESLICE      50 /* 50 milliseconds */

#define CONFIGURE_MAXIMUM_TASKS 4
#define CONFIGURE_RTEMS_INIT_TASKS_TABLE
```

This system will begin execution with the single initialization task named `Init`. It will be configured to have both a console device driver (for standard I/O) and a clock tick device driver.

For each configuration parameter in the configuration tables, the macro corresponding to that field is discussed. Most systems can be easily configured using the `rtems/confdefs.h` mechanism.

The `CONFIGURE_INIT` constant must be defined in order to make `rtems/confdefs.h` instantiate the configuration data structures. This can only be defined in one source file per application that includes `rtems/confdefs.h` or the symbol table will be instantiated multiple times and linking errors produced.

The user should be aware that the defaults are intentionally set as low as possible. By default, no application resources are configured. The `rtems/confdefs.h` file ensures that at least one application tasks or thread is configured and that at least one of the initialization task/thread tables is configured.

The `rtems/confdefs.h` file estimates the amount of memory required for the RTEMS Executive Workspace. This estimate is only as accurate as the information given to

`rtems/confdefs.h` and may be either too high or too low for a variety of reasons. Some of the reasons that `rtems/confdefs.h` may reserve too much memory for RTEMS are:

- All tasks/threads are assumed to be floating point.

Conversely, there are many more reasons, the resource estimate could be too low:

- Task/thread stacks greater than minimum size must be accounted for explicitly by developer.
- Memory for messages is not included.
- Device driver requirements are not included.
- Network stack requirements are not included.
- Requirements for add-on libraries are not included.

In general, `rtems/confdefs.h` is very accurate when given enough information. However, it is quite easy to use a library and not account for its resources.

The following subsection list all of the constants which can be set by the user.

23.2.1 Library Support Definitions

This section defines the file system and IO library related configuration parameters supported by `rtems/confdefs.h`.

- `CONFIGURE_MALLOC_STATISTICS` is defined when the application wishes to enable the gathering of more detailed statistics on the C Malloc Family of routines.
- `CONFIGURE_MALLOC_BSP_SUPPORTS_SBRK` is defined by a BSP to indicate that it does not allocate all available memory to the C Program Heap used by the Malloc Family of routines. If defined, when `malloc()` is unable to allocate memory, it will call the BSP supplied `sbrk()` to obtain more memory.
- `CONFIGURE_LIBIO_MAXIMUM_FILE_DESCRIPTOR` is set to the maximum number of files that can be concurrently open. Libio requires a Classic RTEMS semaphore for each file descriptor as well as one global one. The default value is 3 file descriptors which is enough to support standard input, output, and error output.
- `CONFIGURE_TERMIOS_DISABLED` is defined if the software implementing POSIX termios functionality is not going to be used by this application. By default, this is not defined and resources are reserved for the termios functionality.
- `CONFIGURE_NUMBER_OF_TERMIOS_PORTS` is set to the number of ports using the termios functionality. Each concurrently active termios port requires resources. By default, this is set to 1 so a console port can be used.
- `CONFIGURE_HAS_OWN_MOUNT_TABLE` is defined when the application provides their own filesystem mount table. The mount table is an array of `rtems_filesystem_mount_table_t` entries pointed to by the global variable `rtems_filesystem_mount_table`. The number of entries in this table is in an integer variable named `rtems_filesystem_mount_table_t`.
- `CONFIGURE_USE_IMFS_AS_BASE_FILESYSTEM` is defined if the application wishes to use the full functionality IMFS. By default, the miniIMFS is used. The miniIMFS is a minimal functionality subset of the In-Memory FileSystem (IMFS). The miniIMFS

is comparable in functionality to the pseudo-filesystem name space provided before RTEMS release 4.5.0. The miniIMFS supports only directories and device nodes and is smaller in executable code size than the full IMFS.

- `CONFIGURE_USE_DEVFS_AS_BASE_FILESYSTEM` is defined if the application wishes to use the device-only filesystem. The device-only filesystem supports only device nodes and is smaller in executable code size than the full IMFS and miniIMFS.
- `CONFIGURE_APPLICATION_DISABLE_FILESYSTEM` is defined if the application does not intend to use any kind of filesystem supports (including printf family).
- `CONFIGURED_STACK_CHECKER_ENABLED` is defined when the application wishes to enable run-time stack bounds checking. This increases the time required to create tasks as well as adding overhead to each context switch. By default, this is not defined and thus stack checking is disabled. NOTE: In 4.9 and older, this was named `STACK_CHECKER_ON`

23.2.2 Basic System Information

This section defines the general system configuration parameters supported by `rtems/confdefs.h`.

- `CONFIGURE_HAS_OWN_CONFIGURATION_TABLE` should only be defined if the application is providing their own complete set of configuration tables.
- `CONFIGURE_EXECUTIVE_RAM_WORK_AREA` is the base address of the RTEMS RAM Workspace. By default, this value is NULL indicating that the BSP is to determine the location of the RTEMS RAM Workspace.
- `CONFIGURE_UNIFIED_WORK_AREAS` configures RTEMS to use a single memory pool for the RTEMS Workspace and C Program Heap. If not defined, there will be separate memory pools for the RTEMS Workspace and C Program Heap. Having separate pools does have some advantages in the event a task blows a stack or writes outside its memory area. However, in low memory systems the overhead of the two pools plus the potential for unused memory in either pool is very undesirable.

In high memory environments, this is desirable when you want to use the RTEMS "unlimited" objects option. You will be able to create objects until you run out of all available memory rather than just until you run out of RTEMS Workspace.

- `CONFIGURE_MICROSECONDS_PER_TICK` is the length of time between clock ticks. By default, this is set to 10000 microseconds.
- `CONFIGURE_TICKS_PER_TIMESLICE` is the length of the timeslice quantum in ticks for each task. By default, this is 50.
- `CONFIGURE_MAXIMUM_PRIORITY` is the maximum numeric priority of any task in the system and one less than the number of priority levels in the system. The numerically greatest priority is the logically lowest priority in the system and will thus be used by the IDLE task. Valid values for this configuration parameter must be one (1) less than a power of two (2) between 4 and 256 inclusively. In other words, valid values are 3, 7, 31, 63, 127, and 255. Reducing the number of priorities in the system reduces the amount of memory allocated from the RTEMS Workspace. By default, RTEMS supports 256 priority levels ranging from 0 to 255 so the default value for this field is 255.

- `CONFIGURE_MINIMUM_STACK_SIZE` is set to the number of bytes the application wants the minimum stack size to be for every task or thread in the system. By default, this is set to the recommended minimum stack size for this processor.
- `CONFIGURE_INTERRUPT_STACK_SIZE` is set to the size of the interrupt stack. The interrupt stack size is usually set by the BSP but since this memory may be allocated from the RTEMS Ram Workspace, it must be accounted for. The default for this field is the configured minimum stack size. [NOTE: In some BSPs, changing this constant does NOT change the size of the interrupt stack, only the amount of memory reserved for it.] If not specified, the interrupt stack will be of minimum size. The default value is the configured minimum stack size.
- `CONFIGURE_TASK_STACK_ALLOCATOR` may point to a user provided routine to allocate task stacks. The default value for this field is NULL which indicates that task stacks will be allocated from the RTEMS Workspace.
- `CONFIGURE_TASK_STACK_DEALLOCATOR` may point to a user provided routine to free task stacks. The default value for this field is NULL which indicates that task stacks will be allocated from the RTEMS Workspace.
- `CONFIGURE_ZERO_WORKSPACE_AUTOMATICALLY` indicates whether RTEMS should zero the RTEMS Workspace and C Program Heap as part of its initialization. If set to TRUE, the Workspace is zeroed. Otherwise, it is not. Unless overridden by the BSP, the default value for this field is FALSE.
- `CONFIGURE_MESSAGE_BUFFERS_FOR_QUEUE` is a helper macro which is used to assist in computing the total amount of memory required for message buffers. Each message queue will have its own configuration with maximum message size and maximum number of pending messages. The interface for this macro is as follows:

```
CONFIGURE_MESSAGE_BUFFERS_FOR_QUEUE(max_messages, size_per)
```

Where `max_messages` is the maximum number of pending messages and `size_per` is the size in bytes of the user message.

- `CONFIGURE_MESSAGE_BUFFER_MEMORY` is set to the number of bytes the application requires to be reserved for pending message queue buffers. This value should include memory for all buffers across all APIs. The default value is 0.

The following illustrates how the help macro `CONFIGURE_MESSAGE_BUFFERS_FOR_QUEUE` can be used to assist in calculating the message buffer memory required. In this example, there are two message queues used in this application. The first message queue has maximum of 24 pending messages with the message structure defined by the type `one_message_type`. The other message queue has maximum of 500 pending messages with the message structure defined by the type `other_message_type`.

```
#define CONFIGURE_MESSAGE_BUFFERS_FOR_QUEUE \
(CONFIGURE_MESSAGE_BUFFERS_FOR_QUEUE( \
    24, sizeof(one_message_type) + \
    CONFIGURE_MESSAGE_BUFFERS_FOR_QUEUE( \
        500, sizeof(other_message_type) \
    )
```

- `CONFIGURE_MEMORY_OVERHEAD` is set to the number of kilobytes the application wishes to add to the requirements calculated by `rtems/confdefs.h`. The default value is 0.
- `CONFIGURE_EXTRA_TASK_STACKS` is set to the number of bytes the applications wishes to add to the task stack requirements calculated by `rtems/confdefs.h`. This parameter is very important. If the application creates tasks with stacks larger than the minimum, then that memory is NOT accounted for by `rtems/confdefs.h`. The default value is 0.

NOTE: The required size of the Executive RAM Work Area is calculated automatically when using the `rtems/confdefs.h` mechanism.

23.2.3 Idle Task Configuration

This section defines the IDLE task related configuration parameters supported by `rtems/confdefs.h`.

- `CONFIGURE_IDLE_TASK_BODY` is set to the method name corresponding to the application specific IDLE thread body. If not specified, the BSP or RTEMS default IDLE thread body will be used. The default value is NULL.
- `CONFIGURE_IDLE_TASK_STACK_SIZE` is set to the desired stack size for the IDLE task. If not specified, the IDLE task will have a stack of minimum size. The default value is the configured minimum stack size.
- `CONFIGURE_IDLE_TASK_INITIALIZES_APPLICATION` is set to indicate that the user has configured **NO** user initialization tasks or threads and that the user provided IDLE task will perform application initialization and then transform itself into an IDLE task. If you use this option be careful, the user IDLE task **CANNOT** block at all during the initialization sequence. Further, once application initialization is complete, it must make itself preemptible and enter an IDLE body loop. By default, this is not the mode of operation and the user is assumed to provide one or more initialization tasks.

23.2.4 Device Driver Table

This section defines the configuration parameters related to the automatic generation of a Device Driver Table. As `rtems/confdefs.h` only is aware of a small set of standard device drivers, the generated Device Driver Table is suitable for simple applications with no custom device drivers.

- `CONFIGURE_HAS_OWN_DEVICE_DRIVER_TABLE` is defined if the application wishes to provide their own Device Driver Table. The table generated is an array of `rtems_driver_address_table` entries named `Device_drivers`. By default, this is not defined indicating the `rtems/confdefs.h` is providing the device driver table.
- `CONFIGURE_MAXIMUM_DRIVERS` is defined as the number of device drivers per node. By default, this is set to 10.
- `CONFIGURE_MAXIMUM_DEVICES` is defined to the number of individual devices that may be registered in the system. By default, this is set to 4.
- `CONFIGURE_APPLICATION_NEEDS_CONSOLE_DRIVER` is defined if the application wishes to include the Console Device Driver. This device driver is responsible for

providing standard input and output using `"/dev/console"`. By default, this is not defined.

- `CONFIGURE_APPLICATION_NEEDS_CLOCK_DRIVER` is defined if the application wishes to include the Clock Device Driver. This device driver is responsible for providing a regular interrupt which invokes the `rtems_clock_tick` directive. By default, this is not defined.
- `CONFIGURE_APPLICATION_NEEDS_TIMER_DRIVER` is defined if the application wishes to include the Timer Driver. This device driver is used to benchmark execution times by the RTEMS Timing Test Suites. By default, this is not defined.
- `CONFIGURE_APPLICATION_DOES_NOT_NEED_CLOCK_DRIVER` is defined when the application does **NOT** want the Clock Device Driver and is **NOT** using the Timer Driver. The inclusion or exclusion of the Clock Driver must be explicit in typical user applications. This is intended to prevent the common user error of using the Hello World example as the baseline for an application and leaving out a clock tick source.
- `CONFIGURE_APPLICATION_NEEDS_RTC_DRIVER` is defined if the application wishes to include the Real-Time Clock Driver. By default, this is not defined.
- `CONFIGURE_APPLICATION_NEEDS_WATCHDOG_DRIVER` is defined if the application wishes to include the Watchdog Driver. By default, this is not defined.
- `CONFIGURE_APPLICATION_NEEDS_FRAME_BUFFER_DRIVER` is defined if the application wishes to include the BSP's Frame Buffer Device Driver. Most BSPs do not provide a Frame Buffer Device Driver. If this is defined and the BSP does not have this device driver, then the user will get a link time error for an undefined symbol. By default, this is not defined.
- `CONFIGURE_APPLICATION_NEEDS_STUB_DRIVER` is defined if the application wishes to include the Stub Device Driver. This device driver simply provides entry points that return successful and is primarily a test fixture. By default, this is not defined.
- `CONFIGURE_BSP_PREREQUISITE_DRIVERS` is defined if the BSP has device drivers it needs to include in the Device Driver Table. This should be defined to the set of device driver entries that will be placed in the table at the **FRONT** of the Device Driver Table and initialized before any other drivers **INCLUDING** any application prerequisite drivers. By default, this is not defined.
- `CONFIGURE_APPLICATION_PREREQUISITE_DRIVERS` is defined if the application has device drivers it needs to include in the Device Driver Table. This should be defined to the set of device driver entries that will be placed in the table at the **FRONT** of the Device Driver Table and initialized before any other drivers **EXCEPT** any BSP prerequisite drivers. By default, this is not defined.
- `CONFIGURE_APPLICATION_EXTRA_DRIVERS` is defined if the application has device drivers it needs to include in the Device Driver Table. This should be defined to the set of device driver entries that will be placed in the table at the **END** of the Device Driver Table. By default, this is not defined.

23.2.5 Multiprocessing Configuration

This section defines the multiprocessing related system configuration parameters supported by `rtems/confdefs.h`. This class of Configuration Constants are only applicable if `CONFIGURE_MP_APPLICATION` is defined.

- `CONFIGURE_HAS_OWN_MULTIPROCESSING_TABLE` is defined if the application wishes to provide their own Multiprocessing Configuration Table. The generated table is named `Multiprocessing_configuration`. By default, this is not defined.
- `CONFIGURE_MP_NODE_NUMBER` is the node number of this node in a multiprocessor system. The default node number is `NODE_NUMBER` which is set directly in RTEMS test Makefiles.
- `CONFIGURE_MP_MAXIMUM_NODES` is the maximum number of nodes in a multiprocessor system. The default is 2.
- `CONFIGURE_MP_MAXIMUM_GLOBAL_OBJECTS` is the maximum number of concurrently active global objects in a multiprocessor system. The default is 32.
- `CONFIGURE_MP_MAXIMUM_PROXIES` is the maximum number of concurrently active thread/task proxies in a multiprocessor system. The default is 32.
- `CONFIGURE_MP_MPCI_TABLE_POINTER` is the pointer to the MPCIE Configuration Table. The default value of this field is `&MPCIE_table`.

23.2.6 Classic API Configuration

This section defines the Classic API related system configuration parameters supported by `rtems/confdefs.h`.

- `CONFIGURE_MAXIMUM_TASKS` is the maximum number of Classic API tasks that can be concurrently active. The default for this field is 0.
- `CONFIGURE_DISABLE_CLASSIC_API_NOTEPADS` should be defined if the user does not want to have support for Classic API Notepads in their application. By default, this is not defined and Classic API Notepads are supported.
- `CONFIGURE_MAXIMUM_TIMERS` is the maximum number of Classic API timers that can be concurrently active. The default for this field is 0.
- `CONFIGURE_MAXIMUM_SEMAPHORES` is the maximum number of Classic API semaphores that can be concurrently active. The default for this field is 0.
- `CONFIGURE_MAXIMUM_MESSAGE_QUEUES` is the maximum number of Classic API message queues that can be concurrently active. The default for this field is 0.
- `CONFIGURE_MAXIMUM_PARTITIONS` is the maximum number of Classic API partitions that can be concurrently active. The default for this field is 0.
- `CONFIGURE_MAXIMUM_REGIONS` is the maximum number of Classic API regions that can be concurrently active. The default for this field is 0.
- `CONFIGURE_MAXIMUM_PORTS` is the maximum number of Classic API ports that can be concurrently active. The default for this field is 0.
- `CONFIGURE_MAXIMUM_PERIODS` is the maximum number of Classic API rate monotonic periods that can be concurrently active. The default for this field is 0.
- `CONFIGURE_MAXIMUM_USER_EXTENSIONS` is the maximum number of Classic API user extensions that can be concurrently active. The default for this field is 0.

23.2.7 Classic API Initialization Tasks Table Configuration

The `rtems/confdefs.h` configuration system can automatically generate an Initialization Tasks Table named `Initialization_tasks` with a single entry. The following parameters control the generation of that table.

- `CONFIGURE_RTEMS_INIT_TASKS_TABLE` is defined if the user wishes to use a Classic RTEMS API Initialization Task Table. The application may choose to use the initialization tasks or threads table from another API. By default, this field is not defined as the user MUST select their own API for initialization tasks.
- `CONFIGURE_HAS_OWN_INIT_TASK_TABLE` is defined if the user wishes to define their own Classic API Initialization Tasks Table. This table should be named `Initialization_tasks`. By default, this is not defined.
- `CONFIGURE_INIT_TASK_NAME` is the name of the single initialization task defined by the Classic API Initialization Tasks Table. By default the value is `rtems_build_name('U', 'I', '1', ' ')`.
- `CONFIGURE_INIT_TASK_STACK_SIZE` is the stack size of the single initialization task defined by the Classic API Initialization Tasks Table. By default value is the configured minimum stack size.
- `CONFIGURE_INIT_TASK_PRIORITY` is the initial priority of the single initialization task defined by the Classic API Initialization Tasks Table. By default the value is 1 which is the highest priority in the Classic API.
- `CONFIGURE_INIT_TASK_ATTRIBUTES` is the task attributes of the single initialization task defined by the Classic API Initialization Tasks Table. By default the value is `RTEMS_DEFAULT_ATTRIBUTES`.
- `CONFIGURE_INIT_TASK_ENTRY_POINT` is the entry point (a.k.a. function name) of the single initialization task defined by the Classic API Initialization Tasks Table. By default the value is `Init`.
- `CONFIGURE_INIT_TASK_INITIAL_MODES` is the initial execution mode of the single initialization task defined by the Classic API Initialization Tasks Table. By default the value is `RTEMS_NO_PREEMPT`.
- `CONFIGURE_INIT_TASK_ARGUMENTS` is the task argument of the single initialization task defined by the Classic API Initialization Tasks Table. By default the value is 0.

23.2.8 POSIX API Configuration

The parameters in this section are used to configure resources for the RTEMS POSIX API. They are only relevant if the POSIX API is enabled at configure time using the `--enable-posix` option.

- `CONFIGURE_MAXIMUM_POSIX_THREADS` is the maximum number of POSIX API threads that can be concurrently active. The default is 0.
- `CONFIGURE_MAXIMUM_POSIX_MUTEXES` is the maximum number of POSIX API mutexes that can be concurrently active. The default is 0.
- `CONFIGURE_MAXIMUM_POSIX_CONDITION_VARIABLES` is the maximum number of POSIX API condition variables that can be concurrently active. The default is 0.

- `CONFIGURE_MAXIMUM_POSIX_KEYS` is the maximum number of POSIX API keys that can be concurrently active. The default is 0.
- `CONFIGURE_MAXIMUM_POSIX_TIMERS` is the maximum number of POSIX API timers that can be concurrently active. The default is 0.
- `CONFIGURE_MAXIMUM_POSIX_QUEUED_SIGNALS` is the maximum number of POSIX API queued signals that can be concurrently active. The default is 0.
- `CONFIGURE_MAXIMUM_POSIX_MESSAGE_QUEUES` is the maximum number of POSIX API message queues that can be concurrently active. The default is 0.
- `CONFIGURE_MAXIMUM_POSIX_SEMAPHORES` is the maximum number of POSIX API semaphores that can be concurrently active. The default is 0.

23.2.9 POSIX Initialization Threads Table Configuration

The `rtems/confdefs.h` configuration system can automatically generate a POSIX Initialization Threads Table named `POSIX_initialization_threads` with a single entry. The following parameters control the generation of that table.

- `CONFIGURE_POSIX_INIT_THREAD_TABLE` is defined if the user wishes to use a POSIX API Initialization Threads Table. The application may choose to use the initialization tasks or threads table from another API. By default, this field is not defined as the user MUST select their own API for initialization tasks.
- `CONFIGURE_POSIX_HAS_OWN_INIT_THREAD_TABLE` is defined if the user wishes to define their own POSIX API Initialization Threads Table. This table should be named `POSIX_initialization_threads`. By default, this is not defined.
- `CONFIGURE_POSIX_INIT_THREAD_ENTRY_POINT` is the entry point (a.k.a. function name) of the single initialization thread defined by the POSIX API Initialization Threads Table. By default the value is `POSIX_Init`.
- `CONFIGURE_POSIX_INIT_THREAD_STACK_SIZE` is the stack size of the single initialization thread defined by the POSIX API Initialization Threads Table. By default value is twice the configured minimum stack size.

23.2.10 ITRON API Configuration

The parameters in this section are used to configure resources for the RTEMS ITRON API. They are only relevant if the POSIX API is enabled at configure time using the `--enable-itron` option.

- `CONFIGURE_MAXIMUM_ITRON_TASKS` is the maximum number of ITRON API tasks that can be concurrently active. The default is 0.
- `CONFIGURE_MAXIMUM_ITRON_SEMAPHORES` is the maximum number of ITRON API semaphores that can be concurrently active. The default is 0.
- `CONFIGURE_MAXIMUM_ITRON_EVENTFLAGS` is the maximum number of ITRON API eventflags that can be concurrently active. The default is 0.
- `CONFIGURE_MAXIMUM_ITRON_MAILBOXES` is the maximum number of ITRON API mailboxes that can be concurrently active. The default is 0.
- `CONFIGURE_MAXIMUM_ITRON_MESSAGE_BUFFERS` is the maximum number of ITRON API message buffers that can be concurrently active. The default is 0.

- `CONFIGURE_MAXIMUM_ITRON_PORTS` is the maximum number of ITRON API ports that can be concurrently active. The default is 0.
- `CONFIGURE_MAXIMUM_ITRON_MEMORY_POOLS` is the maximum number of ITRON API memory pools that can be concurrently active. The default is 0.
- `CONFIGURE_MAXIMUM_ITRON_FIXED_MEMORY_POOLS` is the maximum number of ITRON API fixed memory pools that can be concurrently active. The default is 0.

23.2.11 ITRON Initialization Task Table Configuration

The `rtems/confdefs.h` configuration system can automatically generate an ITRON Initialization Tasks Table named `ITRON_Initialization_tasks` with a single entry. The following parameters control the generation of that table.

- `CONFIGURE_ITRON_INIT_TASK_TABLE` is defined if the user wishes to use a ITRON API Initialization Tasks Table. The application may choose to use the initialization tasks or threads table from another API. By default, this field is not defined as the user MUST select their own API for initialization tasks.
- `CONFIGURE_ITRON_HAS_OWN_INIT_TASK_TABLE` is defined if the user wishes to define their own ITRON API Initialization Tasks Table. This table should be named `ITRON_Initialization_tasks`. By default, this is not defined.
- `CONFIGURE_ITRON_INIT_TASK_ENTRY_POINT` is the entry point (a.k.a. function name) of the single initialization task defined by the ITRON API Initialization Tasks Table. By default the value is `ITRON_Init`.
- `CONFIGURE_ITRON_INIT_TASK_ATTRIBUTES` is the attribute set of the single initialization task defined by the ITRON API Initialization Tasks Table. By default the value is `TA_HLNG`.
- `CONFIGURE_ITRON_INIT_TASK_PRIORITY` is the initial priority of the single initialization task defined by the ITRON API Initialization Tasks Table. By default the value is 1 which is the highest priority in the ITRON API.
- `CONFIGURE_ITRON_INIT_TASK_STACK_SIZE` is the stack size of the single initialization task defined by the ITRON API Initialization Tasks Table. By default value is the configured minimum stack size.

23.2.12 Ada Tasks

This section defines the system configuration parameters supported by `rtems/confdefs.h` related to configuring RTEMS to support a task using Ada tasking with GNAT.

- `CONFIGURE_GNAT_RTEMS` is defined to inform RTEMS that the GNAT Ada run-time is to be used by the application. This configuration parameter is critical as it makes `rtems/confdefs.h` configure the resources (mutexes and keys) used implicitly by the GNAT run-time. By default, this parameter is not defined.
- `CONFIGURE_MAXIMUM_ADA_TASKS` is the number of Ada tasks that can be concurrently active in the system. By default, when `CONFIGURE_GNAT_RTEMS` is defined, this is set to 20.
- `CONFIGURE_MAXIMUM_FAKE_ADA_TASKS` is the number of "fake" Ada tasks that can be concurrently active in the system. A "fake" Ada task is a non-Ada task that makes calls back into Ada code and thus implicitly uses the Ada run-time.

23.2.13 PCI Library

This section defines the system configuration parameters supported by `rtems/confdefs.h` related to configuring the PCI Library for RTEMS.

The PCI Library startup behaviour can be configured in four different ways depending on how `CONFIGURE_PCI_CONFIG_LIB` is defined:

- `PCI_LIB_AUTO` is used to enable the PCI auto configuration software. PCI will be automatically probed, PCI buses enumerated, all devices and bridges will be initialized using Plug & Play software routines. The PCI device tree will be populated based on the PCI devices found in the system, PCI devices will be configured by allocating address region resources automatically in PCI space according to the BSP or host bridge driver set up.
- `PCI_LIB_READ` is used to enable the PCI read configuration software. The current PCI configuration is read to create the RAM representation (the PCI device tree) of the PCI devices present. PCI devices are assumed to already have been initialized and PCI buses enumerated, it is therefore required that a BIOS or a boot loader has set up configuration space prior to booting into RTEMS.
- `PCI_LIB_STATIC` is used to enable the PCI static configuration software. The user provides a PCI tree with information how all PCI devices are to be configured at compile time by linking in a custom `struct pci_bus pci_hb` tree. The static PCI library will not probe PCI for devices, instead it will assume that all devices defined by the user is present, it will enumerate the PCI buses and configure all PCI devices in static configuration accordingly. Since probe and allocation software is not needed the startup is faster, have smaller footprint and does not require dynamic memory allocation.
- `PCI_LIB_PERIPHERAL` is used to enable the PCI peripheral configuration. It is similar to `PCI_LIB_STATIC`, but it will never write the configuration to the PCI devices since PCI peripherals are not allowed to access PCI configuration space.

Note that selecting `PCI_LIB_STATIC` or `PCI_LIB_PERIPHERAL` but not defining `pci_hb` will result in link errors. Note also that in these modes Plug & Play is not performed.

23.3 Configuration Table

The RTEMS Configuration Table is used to tailor an application for its specific needs. For example, the user can configure the number of device drivers or which APIs may be used. The address of the user-defined Configuration Table is passed as an argument to the `rtems_initialize_executive` directive, which MUST be the first RTEMS directive called. The RTEMS Configuration Table is defined in the following C structure:

```

typedef struct {
    void                *work_space_start;
    uintptr_t           work_space_size;
    uint32_t            maximum_extensions;
    uint32_t            microseconds_per_tick;
    uint32_t            ticks_per_timeslice;
    void                (*idle_task)( void );
    uint32_t            idle_task_stack_size;
    uint32_t            interrupt_stack_size;
    void *              (*stack_allocate_hook)( size_t );
    void                (*stack_free_hook)( void * );
    bool                do_zero_of_workspace;
    uint32_t            maximum_drivers;
    uint32_t            number_of_device_drivers;
    rtems_driver_address_table *Device_driver_table;
    uint32_t            number_of_initial_extensions;
    rtems_extensions_table *User_extension_table;
#if defined(RTEMS_MULTIPROCESSING)
    rtems_multiprocessing_table *User_multiprocessing_table;
#endif
    rtems_api_configuration_table *RTEMS_api_configuration;
    posix_api_configuration_table *POSIX_api_configuration;
    itron_api_configuration      *ITRON_api_configuration;
} rtems_configuration_table;

```

work_space_start is the address of the RTEMS RAM Workspace. This area contains items such as the various object control blocks (TCBs, QCBs, ...) and task stacks. If the address is not aligned on a four-word boundary, then RTEMS will invoke the fatal error handler during `rtems_initialize_executive`. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_EXECUTIVE_RAM_WORK_AREA` which defaults to `NULL`. Normally, this field should be configured as `NULL` as BSPs will assign memory for the RTEMS RAM Workspace as part of system initialization.

work_space_size is the calculated size of the RTEMS RAM Workspace. The section [Sizing the RTEMS RAM Workspace](#) details how to arrive at this number. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_EXECUTIVE_RAM_SIZE` and is calculated based on the other system configuration settings.

microseconds_per_tick is number of microseconds per clock tick. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MICROSECONDS_PER_TICK`. If not defined by the applica-

	tion, then the <code>CONFIGURE_MICROSECONDS_PER_TICK</code> macro defaults to 10000 (10 milliseconds).
ticks_per_timeslice	is the number of clock ticks for a timeslice. When using the <code>rtems/confdefs.h</code> mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro <code>CONFIGURE_TICKS_PER_TIMESLICE</code> .
idle_task	is the address of the optional user provided routine which is used as the system's IDLE task. If this field is not NULL, then the RTEMS default IDLE task is not used. This field may be NULL to indicate that the default IDLE is to be used. When using the <code>rtems/confdefs.h</code> mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro <code>CONFIGURE_IDLE_TASK_BODY</code> .
idle_task_stack_size	is the size of the RTEMS idle task stack in bytes. If this number is less than the configured minimum stack size, then the idle task's stack will be set to the minimum. When using the <code>rtems/confdefs.h</code> mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro <code>CONFIGURE_IDLE_TASK_STACK_SIZE</code> .
interrupt_stack_size	is the size of the RTEMS interrupt stack in bytes. If this number is less than configured minimum stack size, then the interrupt stack will be set to the minimum. When using the <code>rtems/confdefs.h</code> mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro <code>CONFIGURE_INTERRUPT_STACK_SIZE</code> .
stack_allocate_hook	may point to a user provided routine to allocate task stacks. The default is to allocate task stacks from the RTEMS Workspace. When using the <code>rtems/confdefs.h</code> mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro <code>CONFIGURE_TASK_STACK_ALLOCATOR</code> .
stack_free_hook	may point to a user provided routine to free task stacks. The default is to allocate task stacks from the RTEMS Workspace. When using the <code>rtems/confdefs.h</code> mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro <code>CONFIGURE_TASK_STACK_DEALLOCATOR</code> .
do_zero_of_workspace	indicates whether RTEMS should zero the RTEMS Workspace and C Program Heap as part of its initialization. If set to TRUE, the Workspace is zeroed. Otherwise, it is not. When using the <code>rtems/confdefs.h</code> mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro <code>CONFIGURE_ZERO_WORKSPACE_AUTOMATICALLY</code> .
maximum_drivers	is the maximum number of device drivers that can be registered. When using the <code>rtems/confdefs.h</code> mechanism for configuring an

RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_DRIVERS`.

number_of_device_drivers

is the number of device drivers for the system. There should be the same number of entries in the Device Driver Table. If this field is zero, then the `User_driver_address_table` entry should be `NULL`. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field is calculated automatically based on the number of entries in the Device Driver Table. This calculation is based on the assumption that the Device Driver Table is named `Device_drivers` and defined in C. This table may be generated automatically for simple applications using only the device drivers that correspond to the following macros:

- `CONFIGURE_APPLICATION_NEEDS_CONSOLE_DRIVER`
- `CONFIGURE_APPLICATION_NEEDS_CLOCK_DRIVER`
- `CONFIGURE_APPLICATION_NEEDS_TIMER_DRIVER`
- `CONFIGURE_APPLICATION_NEEDS_RTC_DRIVER`
- `CONFIGURE_APPLICATION_NEEDS_STUB_DRIVER`

Note that network device drivers are not configured in the Device Driver Table.

Device_driver_table

is the address of the Device Driver Table. This table contains the entry points for each device driver. If the `number_of_device_drivers` field is zero, then this entry should be `NULL`. The format of this table will be discussed below. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the Device Driver Table is assumed to be named `Device_drivers` and defined in C. If the application is providing its own Device Driver Table, then the macro `CONFIGURE_HAS_OWN_DEVICE_DRIVER_TABLE` must be defined to indicate this and prevent `rtems/confdefs.h` from generating the table.

number_of_initial_extensions

is the number of initial user extensions. There should be the same number of entries as in the `User_extension_table`. If this field is zero, then the `User_driver_address_table` entry should be `NULL`. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_NUMBER_OF_INITIAL_EXTENSIONS` which is set automatically by `rtems/confdefs.h` based on the size of the User Extensions Table.

User_extension_table

is the address of the User Extension Table. This table contains the entry points for the static set of optional user extensions. If no user extensions are configured, then this entry should be `NULL`. The format of this table will be discussed below. When using the

`rtems/confdefs.h` mechanism for configuring an RTEMS application, the User Extensions Table is named `Configuration_Initial_Extensions` and defined in `confdefs.h`. It is initialized based on the following macros:

- `CONFIGURE_INITIAL_EXTENSIONS`
- `STACK_CHECKER_EXTENSION`

The application may configure one or more initial user extension sets by setting the `CONFIGURE_INITIAL_EXTENSIONS` macro. By defining the `STACK_CHECKER_EXTENSION` macro, the task stack bounds checking user extension set is automatically included in the application.

User_multiprocessing_table

is the address of the Multiprocessor Configuration Table. This table contains information needed by RTEMS only when used in a multiprocessor configuration. This field must be NULL when RTEMS is used in a single processor configuration. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the Multiprocessor Configuration Table is automatically generated when the `CONFIGURE_MP_APPLICATION` is defined. If `CONFIGURE_MP_APPLICATION` is not defined, the this entry is set to NULL. The generated table has the name `Multiprocessing_configuration`.

RTEMS_api_configuration

is the address of the RTEMS API Configuration Table. This table contains information needed by the RTEMS API. This field should be NULL if the RTEMS API is not used. [NOTE: Currently the RTEMS API is required to support support components such as BSPs and libraries which use this API.] This table is built automatically and this entry filled in, if using the `rtems/confdefs.h` application configuration mechanism. The generated table has the name `Configuration_RTEMS_API`.

POSIX_api_configuration

is the address of the POSIX API Configuration Table. This table contains information needed by the POSIX API. This field should be NULL if the POSIX API is not used. This table is built automatically and this entry filled in, if using the `rtems/confdefs.h` application configuration mechanism. The `rtems/confdefs.h` application mechanism will fill this field in with the address of the `Configuration_POSIX_API` table of POSIX API is configured and NULL if the POSIX API is not configured.

23.4 RTEMS API Configuration Table

The RTEMS API Configuration Table is used to configure the managers which constitute the RTEMS API for a particular application. For example, the user can configure the maximum number of tasks for this application. The RTEMS API Configuration Table is defined in the following C structure:

```
typedef struct {
    uint32_t    maximum_tasks;
    uint32_t    maximum_timers;
    uint32_t    maximum_semaphores;
    uint32_t    maximum_message_queues;
    uint32_t    maximum_partitions;
    uint32_t    maximum_regions;
    uint32_t    maximum_ports;
    uint32_t    maximum_periods;
    uint32_t    maximum_barriers;
    uint32_t    number_of_initialization_tasks;
    rtems_initialization_tasks_table *User_initialization_tasks_table;
} rtems_api_configuration_table;
```

maximum_tasks is the maximum number of tasks that can be concurrently active (created) in the system including initialization tasks. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_TASKS`. If not defined by the application, then the `CONFIGURE_MAXIMUM_TASKS` macro defaults to 0.

maximum_timers is the maximum number of timers that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_TIMERS`. If not defined by the application, then the `CONFIGURE_MAXIMUM_TIMERS` macro defaults to 0.

maximum_semaphores is the maximum number of semaphores that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_SEMAPHORES`. If not defined by the application, then the `CONFIGURE_MAXIMUM_SEMAPHORES` macro defaults to 0.

maximum_message_queues is the maximum number of message queues that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_MESSAGE_QUEUES`. If not defined by the application, then the `CONFIGURE_MAXIMUM_MESSAGE_QUEUES` macro defaults to 0.

maximum_partitions is the maximum number of partitions that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_PARTITIONS`. If not defined by the application, then the `CONFIGURE_MAXIMUM_PARTITIONS` macro defaults to 0.

maximum_regions is the maximum number of regions that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_REGIONS`. If not defined by the application, then the `CONFIGURE_MAXIMUM_REGIONS` macro defaults to 0.

maximum_ports is the maximum number of ports into dual-port memory areas that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_PORTS`. If not defined by the application, then the `CONFIGURE_MAXIMUM_PORTS` macro defaults to 0.

number_of_initialization_tasks

is the number of initialization tasks configured. At least one RTEMS initialization task or POSIX initialization must be configured in order for the user's application to begin executing. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the user must define the `CONFIGURE_RTEMS_INIT_TASKS_TABLE` to indicate that there is one or more RTEMS initialization task. If the application only has one RTEMS initialization task, then the automatically generated Initialization Task Table will be sufficient. The following macros correspond to the single initialization task:

- `CONFIGURE_INIT_TASK_NAME` - is the name of the task. If this macro is not defined by the application, then this defaults to the task name of "UI1 " for User Initialization Task 1.
- `CONFIGURE_INIT_TASK_STACK_SIZE` - is the stack size of the single initialization task. If this macro is not defined by the application, then this defaults to configured minimum stack size.
- `CONFIGURE_INIT_TASK_PRIORITY` - is the initial priority of the single initialization task. If this macro is not defined by the application, then this defaults to 1.
- `CONFIGURE_INIT_TASK_ATTRIBUTES` - is the attributes of the single initialization task. If this macro is not defined by the application, then this defaults to `RTEMS_DEFAULT_ATTRIBUTES`.
- `CONFIGURE_INIT_TASK_ENTRY_POINT` - is the entry point of the single initialization task. If this macro is not defined by the application, then this defaults to the C language routine `Init`.
- `CONFIGURE_INIT_TASK_INITIAL_MODES` - is the initial execution modes of the single initialization task. If this macro is not defined by the application, then this defaults to `RTEMS_NO_PREEMPT`.

- **CONFIGURE_INIT_TASK_ARGUMENTS** - is the argument passed to the of the single initialization task. If this macro is not defined by the application, then this defaults to 0.

has the option to have value for this field corresponds to the setting of the macro .

User_initialization_tasks_table

is the address of the Initialization Task Table. This table contains the information needed to create and start each of the initialization tasks. The format of this table will be discussed below. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro **CONFIGURE_EXECUTIVE_RAM_WORK_AREA**.

23.5 POSIX API Configuration Table

The POSIX API Configuration Table is used to configure the managers which constitute the POSIX API for a particular application. For example, the user can configure the maximum number of threads for this application. The POSIX API Configuration Table is defined in the following C structure:

```
typedef struct {
    void      *(*thread_entry)(void *);
} posix_initialization_threads_table;

typedef struct {
    int      maximum_threads;
    int      maximum_mutexes;
    int      maximum_condition_variables;
    int      maximum_keys;
    int      maximum_timers;
    int      maximum_queued_signals;
    int      maximum_message_queues;
    int      maximum_message_queue_descriptors;
    int      maximum_semaphores;
    int      maximum_barriers;
    int      maximum_rwlocklocks;
    int      maximum_spinlocks;
    int      number_of_initialization_threads;
    posix_initialization_threads_table *User_initialization_tasks_table;
} posix_api_configuration_table;
```

maximum_threads is the maximum number of threads that can be concurrently active (created) in the system including initialization threads. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro **CONFIGURE_MAXIMUM_POSIX_THREADS**. If not defined by the applica-

tion, then the `CONFIGURE_MAXIMUM_POSIX_THREADS` macro defaults to 0.

maximum_mutexes is the maximum number of mutexes that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_POSIX_MUTEXES`. If not defined by the application, then the `CONFIGURE_MAXIMUM_POSIX_MUTEXES` macro defaults to 0.

maximum_condition_variables is the maximum number of condition variables that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_POSIX_CONDITION_VARIABLES`. If not defined by the application, then the `CONFIGURE_MAXIMUM_POSIX_CONDITION_VARIABLES` macro defaults to 0.

maximum_keys is the maximum number of keys that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_POSIX_KEYS`. If not defined by the application, then the `CONFIGURE_MAXIMUM_POSIX_KEYS` macro defaults to 0.

maximum_timers is the maximum number of POSIX timers that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_POSIX_TIMERS`. If not defined by the application, then the `CONFIGURE_MAXIMUM_POSIX_TIMERS` macro defaults to 0.

maximum_queued_signals is the maximum number of queued signals that can be concurrently pending in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_POSIX_QUEUED_SIGNALS`. If not defined by the application, then the `CONFIGURE_MAXIMUM_POSIX_QUEUED_SIGNALS` macro defaults to 0.

maximum_message_queues is the maximum number of POSIX message queues that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_POSIX_MESSAGE_QUEUES`. If not defined by the application, then the `CONFIGURE_MAXIMUM_POSIX_MESSAGE_QUEUES` macro defaults to 0.

maximum_message_queue_descriptors

is the maximum number of POSIX message queue descriptors that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_POSIX_MESSAGE_QUEUE_DESCRIPTOR`s. If not defined by the application, then the `CONFIGURE_MAXIMUM_POSIX_MESSAGE_QUEUE_DESCRIPTOR`s macro defaults to the value of `CONFIGURE_MAXIMUM_POSIX_MESSAGE_QUEUES`

maximum_semaphores

is the maximum number of POSIX semaphore that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_POSIX_SEMAPHORES`. If not defined by the application, then the `CONFIGURE_MAXIMUM_POSIX_SEMAPHORES` macro defaults to 0.

maximum_barriers

is the maximum number of POSIX barriers that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_POSIX_BARRIERS`. If not defined by the application, then the `CONFIGURE_MAXIMUM_POSIX_BARRIERS` macro defaults to 0.

maximum_rwlocks

is the maximum number of POSIX rwlocks that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_POSIX_SPINLOCKS`. If not defined by the application, then the `CONFIGURE_MAXIMUM_POSIX_SPINLOCKS` macro defaults to 0.

maximum_spinlocks

is the maximum number of POSIX spinlocks that can be concurrently active in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MAXIMUM_POSIX_MESSAGE_QUEUES`. If not defined by the application, then the `CONFIGURE_MAXIMUM_POSIX_MESSAGE_QUEUES` macro defaults to 0.

number_of_initialization_threads

is the number of initialization threads configured. At least one initialization threads must be configured. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the user must define the `CONFIGURE_POSIX_INIT_THREAD_TABLE` to indicate that there is one or more POSIX initialization thread. If the application only has one POSIX initialization thread, then the automatically generated POSIX Initialization Thread Table will be sufficient. The following macros correspond to the single initialization task:

- `CONFIGURE_POSIX_INIT_THREAD_ENTRY_POINT` - is the entry point of the thread. If this macro is not defined by the application, then this defaults to the C routine `POSIX_Init`.
- `CONFIGURE_POSIX_INIT_TASK_STACK_SIZE` - is the stack size of the single initialization thread. If this macro is not defined by the application, then this defaults to twice the configured minimum stack size.

User_initialization_threads_table

is the address of the Initialization Threads Table. This table contains the information needed to create and start each of the initialization threads. The format of each entry in this table is defined in the `posix_initialization_threads_table` structure. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the address of the `POSIX_Initialization_threads` structure.

23.6 CPU Dependent Information Table

The CPU Dependent Information Table is used to describe processor dependent information required by RTEMS. This table is generally used to supply RTEMS with information only known by the Board Support Package. The contents of this table are discussed in the CPU Dependent Information Table chapter of the Applications Supplement document for a specific target processor.

The `rtems/confdefs.h` mechanism does not support generating this table. It is normally filled in by the Board Support Package.

23.7 Initialization Task Table

The Initialization Task Table is used to describe each of the user initialization tasks to the Initialization Manager. The table contains one entry for each initialization task the user wishes to create and start. The fields of this data structure directly correspond to arguments to the `rtems_task_create` and `rtems_task_start` directives. The number of entries is found in the `number_of_initialization_tasks` entry in the Configuration Table.

The format of each entry in the Initialization Task Table is defined in the following C structure:

```
typedef struct {
    rtems_name      name;
    size_t          stack_size;
    rtems_task_priority initial_priority;
    rtems_attribute attribute_set;
    rtems_task_entry entry_point;
    rtems_mode      mode_set;
    rtems_task_argument argument;
} rtems_initialization_tasks_table;
```

name is the name of this initialization task.

stack_size	is the size of the stack for this initialization task.
initial_priority	is the priority of this initialization task.
attribute_set	is the attribute set used during creation of this initialization task.
entry_point	is the address of the entry point of this initialization task.
mode_set	is the initial execution mode of this initialization task.
argument	is the initial argument for this initialization task.

A typical declaration for an Initialization Task Table might appear as follows:

```

rtems_initialization_tasks_table
Initialization_tasks[2] = {
    { INIT_1_NAME,
      1024,
      1,
      DEFAULT_ATTRIBUTES,
      Init_1,
      DEFAULT_MODES,
      1

    },
    { INIT_2_NAME,
      1024,
      250,
      FLOATING_POINT,
      Init_2,
      NO_PREEMPT,
      2

    }
};

```

23.8 Driver Address Table

The Device Driver Table is used to inform the I/O Manager of the set of entry points for each device driver configured in the system. The table contains one entry for each device driver required by the application. The number of entries is defined in the `number_of_device_drivers` entry in the Configuration Table. This table is copied to the Device Drive Table during the IO Manager's initialization giving the entries in this table the lower major numbers. The format of each entry in the Device Driver Table is defined in the following C structure:

```

typedef struct {
    rtems_device_driver_entry initialization_entry;
    rtems_device_driver_entry open_entry;
    rtems_device_driver_entry close_entry;
    rtems_device_driver_entry read_entry;

```

```

    rtems_device_driver_entry write_entry;
    rtems_device_driver_entry control_entry;
} rtems_driver_address_table;

```

initialization_entry is the address of the entry point called by `rtems_io_initialize` to initialize a device driver and its associated devices.

open_entry is the address of the entry point called by `rtems_io_open`.

close_entry is the address of the entry point called by `rtems_io_close`.

read_entry is the address of the entry point called by `rtems_io_read`.

write_entry is the address of the entry point called by `rtems_io_write`.

control_entry is the address of the entry point called by `rtems_io_control`.

Driver entry points configured as NULL will always return a status code of `RTEMS_SUCCESSFUL`. No user code will be executed in this situation.

A typical declaration for a Device Driver Table might appear as follows:

```

rtems_driver_address_table Driver_table[2] = {
    { tty_initialize, tty_open,  tty_close,  /* major = 0 */
      tty_read,      tty_write, tty_control
    },
    { lp_initialize, lp_open,    lp_close,   /* major = 1 */
      NULL,          lp_write,  lp_control
    }
};

```

More information regarding the construction and operation of device drivers is provided in the I/O Manager chapter.

23.9 User Extensions Table

The User Extensions Table is used to inform RTEMS of the optional user-supplied static extension set. This table contains one entry for each possible extension. The entries are called at critical times in the life of the system and individual tasks. The application may create dynamic extensions in addition to this single static set. The format of each entry in the User Extensions Table is defined in the following C structure:

```

typedef void          rtems_extension;
typedef void (*rtems_task_create_extension)(
    Thread_Control * /* executing */,
    Thread_Control * /* created */
);
typedef void (*rtems_task_delete_extension)(
    Thread_Control * /* executing */,
    Thread_Control * /* deleted */
);
typedef void (*rtems_task_start_extension)(
    Thread_Control * /* executing */,

```

```

    Thread_Control * /* started */
);
typedef void (*rtems_task_restart_extension)(
    Thread_Control * /* executing */,
    Thread_Control * /* restarted */
);
typedef void (*rtems_task_switch_extension)(
    Thread_Control * /* executing */,
    Thread_Control * /* heir */
);
typedef void (*rtems_task_begin_extension)(
    Thread_Control * /* beginning */
);
typedef void (*rtems_task_exitted_extension)(
    Thread_Control * /* exiting */
);
typedef void (*rtems_fatal_extension)(
    Internal_errors_Source /* the_source */,
    bool /* is_internal */,
    uint32_t /* the_error */
);

typedef struct {
    rtems_task_create_extension    thread_create;
    rtems_task_start_extension    thread_start;
    rtems_task_restart_extension  thread_restart;
    rtems_task_delete_extension   thread_delete;
    rtems_task_switch_extension   thread_switch;
    rtems_task_begin_extension    thread_begin;
    rtems_task_exitted_extension  thread_exitted;
    rtems_fatal_extension         fatal;
} rtems_extensions_table;

```

thread_create is the address of the user-supplied subroutine for the TASK_CREATE extension. If this extension for task creation is defined, it is called from the task_create directive. A value of NULL indicates that no extension is provided.

thread_start is the address of the user-supplied subroutine for the TASK_START extension. If this extension for task initiation is defined, it is called from the task_start directive. A value of NULL indicates that no extension is provided.

thread_restart is the address of the user-supplied subroutine for the TASK_RESTART extension. If this extension for task re-initiation is defined, it is called from the task_restart directive. A value of NULL indicates that no extension is provided.

thread_delete	is the address of the user-supplied subroutine for the TASK_DELETE extension. If this RTEMS extension for task deletion is defined, it is called from the task_delete directive. A value of NULL indicates that no extension is provided.
thread_switch	is the address of the user-supplied subroutine for the task context switch extension. This subroutine is called from RTEMS dispatcher after the current task has been swapped out but before the new task has been swapped in. A value of NULL indicates that no extension is provided. As this routine is invoked after saving the current task's context and before restoring the heir task's context, it is not necessary for this routine to save and restore any registers.
thread_begin	is the address of the user-supplied subroutine which is invoked immediately before a task begins execution. It is invoked in the context of the beginning task. A value of NULL indicates that no extension is provided.
thread_exitted	is the address of the user-supplied subroutine which is invoked when a task exits. This procedure is responsible for some action which will allow the system to continue execution (i.e. delete or restart the task) or to terminate with a fatal error. If this field is set to NULL, the default RTEMS TASK_EXITTED handler will be invoked.
fatal	is the address of the user-supplied subroutine for the FATAL extension. This RTEMS extension of fatal error handling is called from the rtems_fatal_error_occurred directive. If the user's fatal error handler returns or if this entry is NULL then the default RTEMS fatal error handler will be executed.

A typical declaration for a User Extension Table which defines the TASK_CREATE, TASK_DELETE, TASK_SWITCH, and FATAL extension might appear as follows:

```
rtems_extensions_table User_extensions = {
    task_create_extension,
    NULL,
    NULL,
    task_delete_extension,
    task_switch_extension,
    NULL,
    NULL,
    fatal_extension
};
```

More information regarding the user extensions is provided in the User Extensions chapter.

23.10 Multiprocessor Configuration Table

The Multiprocessor Configuration Table contains information needed when using RTEMS in a multiprocessor configuration. Many of the details associated with configuring a multiprocessor system are dependent on the multiprocessor communications layer provided by

the user. The address of the Multiprocessor Configuration Table should be placed in the `User_multiprocessing_table` entry in the primary Configuration Table. Further details regarding many of the entries in the Multiprocessor Configuration Table will be provided in the Multiprocessing chapter.

When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the macro `CONFIGURE_MP_APPLICATION` must be defined to automatically generate the Multiprocessor Configuration Table. If `CONFIGURE_MP_APPLICATION` is not defined, then a NULL pointer is configured as the address of this table.

The format of the Multiprocessor Configuration Table is defined in the following C structure:

```
typedef struct {
    uint32_t      node;
    uint32_t      maximum_nodes;
    uint32_t      maximum_global_objects;
    uint32_t      maximum_proxies;
    uint32_t      extra_mpci_receive_server_stack;
    rtems_mpci_table *User_mpci_table;
} rtems_multiprocessing_table;
```

node is a unique processor identifier and is used in routing messages between nodes in a multiprocessor configuration. Each processor must have a unique node number. RTEMS assumes that node numbers start at one and increase sequentially. This assumption can be used to advantage by the user-supplied MPCIE layer. Typically, this requirement is made when the node numbers are used to calculate the address of inter-processor communication links. Zero should be avoided as a node number because some MPCIE layers use node zero to represent broadcasted packets. Thus, it is recommended that node numbers start at one and increase sequentially. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MP_NODE_NUMBER`. If not defined by the application, then the `CONFIGURE_MP_NODE_NUMBER` macro defaults to the value of the `NODE_NUMBER` macro which is set on the compiler command line by the RTEMS Multiprocessing Test Suites.

maximum_nodes is the number of processor nodes in the system. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MP_MAXIMUM_NODES`. If not defined by the application, then the `CONFIGURE_MP_MAXIMUM_NODES` macro defaults to the value 2.

maximum_global_objects is the maximum number of global objects which can exist at any given moment in the entire system. If this parameter is not the same on all nodes in the system, then a fatal error is generated to inform the user that the system is inconsistent. When using the

`rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MP_MAXIMUM_GLOBAL_OBJECTS`. If not defined by the application, then the `CONFIGURE_MP_MAXIMUM_GLOBAL_OBJECTS` macro defaults to the value 32.

maximum_proxies is the maximum number of proxies which can exist at any given moment on this particular node. A proxy is a substitute task control block which represent a task residing on a remote node when that task blocks on a remote object. Proxies are used in situations in which delayed interaction is required with a remote node. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MP_MAXIMUM_PROXIES`. If not defined by the application, then the `CONFIGURE_MP_MAXIMUM_PROXIES` macro defaults to the value 32.

extra_mpci_receive_server_stack is the extra stack space allocated for the RTEMS MPCIE receive server task in bytes. The MPCIE receive server may invoke nearly all directives and may require extra stack space on some targets.

User_mpci_table is the address of the Multiprocessor Communications Interface Table. This table contains the entry points of user-provided functions which constitute the multiprocessor communications layer. This table must be provided in multiprocessor configurations with all entries configured. The format of this table and details regarding its entries can be found in the next section. When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the value for this field corresponds to the setting of the macro `CONFIGURE_MP_MPCIE_TABLE_POINTER`. If not defined by the application, then the `CONFIGURE_MP_MPCIE_TABLE_POINTER` macro defaults to the address of the table named `MPCIE_table`.

23.11 Multiprocessor Communications Interface Table

This table defines the set of callouts that must be provided by an Multiprocessor Communications Interface implementation.

When using the `rtems/confdefs.h` mechanism for configuring an RTEMS application, the name of this table is assumed to be `MPCIE_table` unless the application sets the `CONFIGURE_MP_MPCIE_TABLE_POINTER` when configuring a multiprocessing system.

The format of this table is defined in the following C structure:

```
typedef struct {
    uint32_t                default_timeout; /* in ticks */
    uint32_t                maximum_packet_size;
    rtems_mpci_initialization_entry initialization;
    rtems_mpci_get_packet_entry   get_packet;
    rtems_mpci_return_packet_entry return_packet;
```

```

    rtems_mpci_send_entry      send_packet;
    rtems_mpci_receive_entry   receive_packet;
} rtems_mpci_table;

```

default_timeout is the default maximum length of time a task should block waiting for a response to a directive which results in communication with a remote node. The maximum length of time is a function the user supplied multiprocessor communications layer and the media used. This timeout only applies to directives which would not block if the operation were performed locally.

maximum_packet_size is the size in bytes of the longest packet which the MPCIE layer is capable of sending. This value should represent the total number of bytes available for a RTEMS interprocessor messages.

initialization is the address of the entry point for the initialization procedure of the user supplied multiprocessor communications layer.

get_packet is the address of the entry point for the procedure called by RTEMS to obtain a packet from the user supplied multiprocessor communications layer.

return_packet is the address of the entry point for the procedure called by RTEMS to return a packet to the user supplied multiprocessor communications layer.

send is the address of the entry point for the procedure called by RTEMS to send an envelope to another node. This procedure is part of the user supplied multiprocessor communications layer.

receive is the address of the entry point for the procedure called by RTEMS to retrieve an envelope containing a message from another node. This procedure is part of the user supplied multiprocessor communications layer.

More information regarding the required functionality of these entry points is provided in the Multiprocessor chapter.

23.12 Determining Memory Requirements

Since memory is a critical resource in many real-time embedded systems, the RTEMS Classic API was specifically designed to allow unused managers to be forcibly excluded from the run-time environment. This allows the application designer the flexibility to tailor RTEMS to most efficiently meet system requirements while still satisfying even the most stringent memory constraints. As result, the size of the RTEMS executive is application dependent.

It is not necessary for RTEMS Application Developers to calculate the amount of memory required for the RTEMS Workspace. This is done automatically by `<rtems/confdefs.h>`. See [Section 23.13 \[Configuring a System Sizing the RTEMS RAM Workspace\]](#), [page 271](#) for more details on how this works. In the event, you are interested in the memory required

for an instance of a particular RTEMS object, please run the test `spsize` on your target board.

RTEMS is built to be a library and any routines that you do not directly or indirectly require in your application will **NOT** be included in your executable image. However, some managers may be explicitly excluded and no attempt to create these instances of these objects will succeed even if they are configured. The following Classic API managers may be optionally excluded:

- signal
- region
- dual ported memory
- event
- multiprocessing
- partition
- timer
- semaphore
- message
- rate monotonic

RTEMS is designed to be built and installed as a library that is linked into the application. As such, much of RTEMS is implemented in such a way that there is a single entry point per source file. This avoids having the linker being forced to pull large object files in their entirety into an application when the application references a single symbol. In the event you discover an RTEMS method that is included in your executable but never entered, please let us know. It might be an opportunity to break a dependency and shrink many RTEMS applications.

RTEMS based applications must somehow provide memory for RTEMS' code and data space. Although RTEMS' data space must be in RAM, its code space can be located in either ROM or RAM. In addition, the user must allocate RAM for the RTEMS RAM Workspace. The size of this area is application dependent and can be calculated using the formula provided in the Memory Requirements chapter of the Applications Supplement document for a specific target processor.

All private RTEMS data variables and routine names used by RTEMS begin with the underscore (`_`) character followed by an upper-case letter. If RTEMS is linked with an application, then the application code should NOT contain any symbols which begin with the underscore character and followed by an upper-case letter to avoid any naming conflicts. All RTEMS directive names should be treated as reserved words.

23.13 Sizing the RTEMS RAM Workspace

The RTEMS RAM Workspace is a user-specified block of memory reserved for use by RTEMS. The application should NOT modify this memory. This area consists primarily of the RTEMS data structures whose exact size depends upon the values specified in the Configuration Table. In addition, task stacks and floating point context areas are dynamically allocated from the RTEMS RAM Workspace.

The `rtems/confdefs.h` mechanism calculates the size of the RTEMS RAM Workspace automatically. It assumes that all tasks are floating point and that all will be allocated the minimum stack space. This calculation also automatically includes the memory that will be allocated for internal use by RTEMS. The following macros may be set by the application to make the calculation of memory required more accurate:

- `CONFIGURE_MEMORY_OVERHEAD`
- `CONFIGURE_EXTRA_TASK_STACKS`

The starting address of the RTEMS RAM Workspace must be aligned on a four-byte boundary. Failure to properly align the workspace area will result in the `rtems_fatal_error_occurred` directive being invoked with the `RTEMS_INVALID_ADDRESS` error code.

The file `<rtems/confdefs.h>` will calculate the value that is specified as the `work_space_size` parameter of the Configuration Table. There are many parameters the application developer can specify to help `<rtems/confdefs.h>` in its calculations. Correctly specifying the application requirements via parameters such as `CONFIGURE_EXTRA_TASK_STACKS` and `CONFIGURE_MAXIMUM_TASKS` is critical.

The allocation of objects can operate in two modes. The default mode has an object number ceiling. No more than the specified number of objects can be allocated from the RTEMS RAM Workspace. The number of objects specified in the particular API Configuration table fields are allocated at initialisation. The second mode allows the number of objects to grow to use the available free memory in the RTEMS RAM Workspace.

The auto-extending mode can be enabled individually for each object type by using the macro `rtems_resource_unlimited`. This takes a value as a parameter, and is used to set the object maximum number field in an API Configuration table. The value is an allocation unit size. When RTEMS is required to grow the object table it is grown by this size. The kernel will return the object memory back to the RTEMS RAM Workspace when an object is destroyed. The kernel will only return an allocated block of objects to the RTEMS RAM Workspace if at least half the allocation size of free objects remain allocated. RTEMS always keeps one allocation block of objects allocated. Here is an example of using `rtems_resource_unlimited`:

```
#define CONFIGURE_MAXIMUM_TASKS rtems_resource_unlimited(5)
```

The user is cautioned that future versions of RTEMS may not have the same memory requirements per object. Although the value calculated is sufficient for a particular target processor and release of RTEMS, memory usage is subject to change across versions and target processors. To avoid problems, the user should accurately specify each configuration parameter and allow `<rtems/confdefs.h>` to calculate the memory requirements. The memory requirements are likely to change each time one of the following events occurs:

- a configuration parameter is modified,
- task or interrupt stack requirements change,
- task floating point attribute is altered,
- RTEMS is upgraded, or
- the target processor is changed.

Failure to provide enough space in the RTEMS RAM Workspace will result in the `rtems_fatal_error_occurred` directive being invoked with the appropriate error code.

24 Multiprocessing Manager

24.1 Introduction

In multiprocessor real-time systems, new requirements, such as sharing data and global resources between processors, are introduced. This requires an efficient and reliable communications vehicle which allows all processors to communicate with each other as necessary. In addition, the ramifications of multiple processors affect each and every characteristic of a real-time system, almost always making them more complicated.

RTEMS addresses these issues by providing simple and flexible real-time multiprocessing capabilities. The executive easily lends itself to both tightly-coupled and loosely-coupled configurations of the target system hardware. In addition, RTEMS supports systems composed of both homogeneous and heterogeneous mixtures of processors and target boards.

A major design goal of the RTEMS executive was to transcend the physical boundaries of the target hardware configuration. This goal is achieved by presenting the application software with a logical view of the target system where the boundaries between processor nodes are transparent. As a result, the application developer may designate objects such as tasks, queues, events, signals, semaphores, and memory blocks as global objects. These global objects may then be accessed by any task regardless of the physical location of the object and the accessing task. RTEMS automatically determines that the object being accessed resides on another processor and performs the actions required to access the desired object. Simply stated, RTEMS allows the entire system, both hardware and software, to be viewed logically as a single system.

24.2 Background

RTEMS makes no assumptions regarding the connection media or topology of a multiprocessor system. The tasks which compose a particular application can be spread among as many processors as needed to satisfy the application's timing requirements. The application tasks can interact using a subset of the RTEMS directives as if they were on the same processor. These directives allow application tasks to exchange data, communicate, and synchronize regardless of which processor they reside upon.

The RTEMS multiprocessor execution model is multiple instruction streams with multiple data streams (MIMD). This execution model has each of the processors executing code independent of the other processors. Because of this parallelism, the application designer can more easily guarantee deterministic behavior.

By supporting heterogeneous environments, RTEMS allows the systems designer to select the most efficient processor for each subsystem of the application. Configuring RTEMS for a heterogeneous environment is no more difficult than for a homogeneous one. In keeping with RTEMS philosophy of providing transparent physical node boundaries, the minimal heterogeneous processing required is isolated in the MPC1 layer.

24.2.1 Nodes

A processor in a RTEMS system is referred to as a node. Each node is assigned a unique non-zero node number by the application designer. RTEMS assumes that node numbers

are assigned consecutively from one to the `maximum_nodes` configuration parameter. The node number, `node`, and the maximum number of nodes, `maximum_nodes`, in a system are found in the Multiprocessor Configuration Table. The `maximum_nodes` field and the number of global objects, `maximum_global_objects`, is required to be the same on all nodes in a system.

The node number is used by RTEMS to identify each node when performing remote operations. Thus, the Multiprocessor Communications Interface Layer (MPCI) must be able to route messages based on the node number.

24.2.2 Global Objects

All RTEMS objects which are created with the `GLOBAL` attribute will be known on all other nodes. Global objects can be referenced from any node in the system, although certain directive specific restrictions (e.g. one cannot delete a remote object) may apply. A task does not have to be global to perform operations involving remote objects. The maximum number of global objects in the system is user configurable and can be found in the `maximum_global_objects` field in the Multiprocessor Configuration Table. The distribution of tasks to processors is performed during the application design phase. Dynamic task relocation is not supported by RTEMS.

24.2.3 Global Object Table

RTEMS maintains two tables containing object information on every node in a multiprocessor system: a local object table and a global object table. The local object table on each node is unique and contains information for all objects created on this node whether those objects are local or global. The global object table contains information regarding all global objects in the system and, consequently, is the same on every node.

Since each node must maintain an identical copy of the global object table, the maximum number of entries in each copy of the table must be the same. The maximum number of entries in each copy is determined by the `maximum_global_objects` parameter in the Multiprocessor Configuration Table. This parameter, as well as the `maximum_nodes` parameter, is required to be the same on all nodes. To maintain consistency among the table copies, every node in the system must be informed of the creation or deletion of a global object.

24.2.4 Remote Operations

When an application performs an operation on a remote global object, RTEMS must generate a Remote Request (RQ) message and send it to the appropriate node. After completing the requested operation, the remote node will build a Remote Response (RR) message and send it to the originating node. Messages generated as a side-effect of a directive (such as deleting a global task) are known as Remote Processes (RP) and do not require the receiving node to respond.

Other than taking slightly longer to execute directives on remote objects, the application is unaware of the location of the objects it acts upon. The exact amount of overhead required for a remote operation is dependent on the media connecting the nodes and, to a lesser degree, on the efficiency of the user-provided MPCI routines.

The following shows the typical transaction sequence during a remote application:

1. The application issues a directive accessing a remote global object.
2. RTEMS determines the node on which the object resides.
3. RTEMS calls the user-provided MPCPI routine `GET_PACKET` to obtain a packet in which to build a RQ message.
4. After building a message packet, RTEMS calls the user-provided MPCPI routine `SEND_PACKET` to transmit the packet to the node on which the object resides (referred to as the destination node).
5. The calling task is blocked until the RR message arrives, and control of the processor is transferred to another task.
6. The MPCPI layer on the destination node senses the arrival of a packet (commonly in an ISR), and calls the `rtems_multiprocessing_announce` directive. This directive readies the Multiprocessing Server.
7. The Multiprocessing Server calls the user-provided MPCPI routine `RECEIVE_PACKET`, performs the requested operation, builds an RR message, and returns it to the originating node.
8. The MPCPI layer on the originating node senses the arrival of a packet (typically via an interrupt), and calls the RTEMS `rtems_multiprocessing_announce` directive. This directive readies the Multiprocessing Server.
9. The Multiprocessing Server calls the user-provided MPCPI routine `RECEIVE_PACKET`, readies the original requesting task, and blocks until another packet arrives. Control is transferred to the original task which then completes processing of the directive.

If an uncorrectable error occurs in the user-provided MPCPI layer, the fatal error handler should be invoked. RTEMS assumes the reliable transmission and reception of messages by the MPCPI and makes no attempt to detect or correct errors.

24.2.5 Proxies

A proxy is an RTEMS data structure which resides on a remote node and is used to represent a task which must block as part of a remote operation. This action can occur as part of the `rtems_semaphore_obtain` and `rtems_message_queue_receive` directives. If the object were local, the task's control block would be available for modification to indicate it was blocking on a message queue or semaphore. However, the task's control block resides only on the same node as the task. As a result, the remote node must allocate a proxy to represent the task until it can be readied.

The maximum number of proxies is defined in the Multiprocessor Configuration Table. Each node in a multiprocessor system may require a different number of proxies to be configured. The distribution of proxy control blocks is application dependent and is different from the distribution of tasks.

24.2.6 Multiprocessor Configuration Table

The Multiprocessor Configuration Table contains information needed by RTEMS when used in a multiprocessor system. This table is discussed in detail in the section Multiprocessor Configuration Table of the Configuring a System chapter.

24.3 Multiprocessor Communications Interface Layer

The Multiprocessor Communications Interface Layer (MPCI) is a set of user-provided procedures which enable the nodes in a multiprocessor system to communicate with one another. These routines are invoked by RTEMS at various times in the preparation and processing of remote requests. Interrupts are enabled when an MPCI procedure is invoked. It is assumed that if the execution mode and/or interrupt level are altered by the MPCI layer, that they will be restored prior to returning to RTEMS.

The MPCI layer is responsible for managing a pool of buffers called packets and for sending these packets between system nodes. Packet buffers contain the messages sent between the nodes. Typically, the MPCI layer will encapsulate the packet within an envelope which contains the information needed by the MPCI layer. The number of packets available is dependent on the MPCI layer implementation.

The entry points to the routines in the user's MPCI layer should be placed in the Multiprocessor Communications Interface Table. The user must provide entry points for each of the following table entries in a multiprocessor system:

- initialization initialize the MPCI
- get_packet obtain a packet buffer
- return_packet return a packet buffer
- send_packet send a packet to another node
- receive_packet called to get an arrived packet

A packet is sent by RTEMS in each of the following situations:

- an RQ is generated on an originating node;
- an RR is generated on a destination node;
- a global object is created;
- a global object is deleted;
- a local task blocked on a remote object is deleted;
- during system initialization to check for system consistency.

If the target hardware supports it, the arrival of a packet at a node may generate an interrupt. Otherwise, the real-time clock ISR can check for the arrival of a packet. In any case, the `rtems_multiprocessing_announce` directive must be called to announce the arrival of a packet. After exiting the ISR, control will be passed to the Multiprocessing Server to process the packet. The Multiprocessing Server will call the `get_packet` entry to obtain a packet buffer and the `receive_entry` entry to copy the message into the buffer obtained.

24.3.1 INITIALIZATION

The INITIALIZATION component of the user-provided MPCI layer is called as part of the `rtems_initialize_executive` directive to initialize the MPCI layer and associated hardware. It is invoked immediately after all of the device drivers have been initialized. This component should adhere to the following prototype:

```
rtms_mpci_entry user_mpci_initialization(  
    rtms_configuration_table *configuration  
);
```

where configuration is the address of the user's Configuration Table. Operations on global objects cannot be performed until this component is invoked. The `INITIALIZATION` component is invoked only once in the life of any system. If the MPCPI layer cannot be successfully initialized, the fatal error manager should be invoked by this routine.

One of the primary functions of the MPCPI layer is to provide the executive with packet buffers. The `INITIALIZATION` routine must create and initialize a pool of packet buffers. There must be enough packet buffers so RTEMS can obtain one whenever needed.

24.3.2 GET_PACKET

The `GET_PACKET` component of the user-provided MPCPI layer is called when RTEMS must obtain a packet buffer to send or broadcast a message. This component should be adhere to the following prototype:

```
rtms_mpci_entry user_mpci_get_packet(  
    rtms_packet_prefix **packet  
);
```

where packet is the address of a pointer to a packet. This routine always succeeds and, upon return, packet will contain the address of a packet. If for any reason, a packet cannot be successfully obtained, then the fatal error manager should be invoked.

RTEMS has been optimized to avoid the need for obtaining a packet each time a message is sent or broadcast. For example, RTEMS sends response messages (RR) back to the originator in the same packet in which the request message (RQ) arrived.

24.3.3 RETURN_PACKET

The `RETURN_PACKET` component of the user-provided MPCPI layer is called when RTEMS needs to release a packet to the free packet buffer pool. This component should be adhere to the following prototype:

```
rtms_mpci_entry user_mpci_return_packet(  
    rtms_packet_prefix *packet  
);
```

where packet is the address of a packet. If the packet cannot be successfully returned, the fatal error manager should be invoked.

24.3.4 RECEIVE_PACKET

The `RECEIVE_PACKET` component of the user-provided MPCPI layer is called when RTEMS needs to obtain a packet which has previously arrived. This component should be adhere to the following prototype:

```
rtms_mpci_entry user_mpci_receive_packet(  
    rtms_packet_prefix **packet  
);
```

where `packet` is a pointer to the address of a packet to place the message from another node. If a message is available, then `packet` will contain the address of the message from another node. If no messages are available, this entry `packet` should contain `NULL`.

24.3.5 SEND_PACKET

The `SEND_PACKET` component of the user-provided MPCPI layer is called when RTEMS needs to send a packet containing a message to another node. This component should be adhere to the following prototype:

```
rtems_mpci_entry user_mpci_send_packet(
    uint32_t      node,
    rtems_packet_prefix **packet
);
```

where `node` is the node number of the destination and `packet` is the address of a packet which containing a message. If the packet cannot be successfully sent, the fatal error manager should be invoked.

If `node` is set to zero, the packet is to be broadcasted to all other nodes in the system. Although some MPCPI layers will be built upon hardware which support a broadcast mechanism, others may be required to generate a copy of the packet for each node in the system.

Many MPCPI layers use the `packet_length` field of the `rtems_packet_prefix` portion of the packet to avoid sending unnecessary data. This is especially useful if the media connecting the nodes is relatively slow.

The `to_convert` field of the `MP_packet_prefix` portion of the packet indicates how much of the packet (in `uint32_t`'s) may require conversion in a heterogeneous system.

24.3.6 Supporting Heterogeneous Environments

Developing an MPCPI layer for a heterogeneous system requires a thorough understanding of the differences between the processors which comprise the system. One difficult problem is the varying data representation schemes used by different processor types. The most pervasive data representation problem is the order of the bytes which compose a data entity. Processors which place the least significant byte at the smallest address are classified as little endian processors. Little endian byte-ordering is shown below:

Byte 3	Byte 2	Byte 1	Byte 0
--------	--------	--------	--------

Conversely, processors which place the most significant byte at the smallest address are classified as big endian processors. Big endian byte-ordering is shown below:

Byte 0	Byte 1	Byte 2	Byte 3
--------	--------	--------	--------

Unfortunately, sharing a data structure between big endian and little endian processors requires translation into a common endian format. An application designer typically chooses the common endian format to minimize conversion overhead.

Another issue in the design of shared data structures is the alignment of data structure elements. Alignment is both processor and compiler implementation dependent. For example, some processors allow data elements to begin on any address boundary, while others impose restrictions. Common restrictions are that data elements must begin on either an even address or on a long word boundary. Violation of these restrictions may cause an exception or impose a performance penalty.

Other issues which commonly impact the design of shared data structures include the representation of floating point numbers, bit fields, decimal data, and character strings. In addition, the representation method for negative integers could be one's or two's complement. These factors combine to increase the complexity of designing and manipulating data structures shared between processors.

RTEMS addressed these issues in the design of the packets used to communicate between nodes. The RTEMS packet format is designed to allow the MPCPI layer to perform all necessary conversion without burdening the developer with the details of the RTEMS packet format. As a result, the MPCPI layer must be aware of the following:

- All packets must begin on a four byte boundary.
- Packets are composed of both RTEMS and application data. All RTEMS data is treated as thirty-two (32) bit unsigned quantities and is in the first `RTEMS_MINIMUM_UNSIGNED32S_TO_CONVERT` thirty-two (32) quantities of the packet.
- The RTEMS data component of the packet must be in native endian format. Endian conversion may be performed by either the sending or receiving MPCPI layer.
- RTEMS makes no assumptions regarding the application data component of the packet.

24.4 Operations

24.4.1 Announcing a Packet

The `rtems_multiprocessing_announce` directive is called by the MPCPI layer to inform RTEMS that a packet has arrived from another node. This directive can be called from an interrupt service routine or from within a polling routine.

24.5 Directives

This section details the additional directives required to support RTEMS in a multiprocessor configuration. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

24.5.1 MULTIPROCESSING_ANNOUNCE - Announce the arrival of a packet

CALLING SEQUENCE:

```
void rtems_multiprocessing_announce( void );
```

DIRECTIVE STATUS CODES:

NONE

DESCRIPTION:

This directive informs RTEMS that a multiprocessing communications packet has arrived from another node. This directive is called by the user-provided MPC1, and is only used in multiprocessor configurations.

NOTES:

This directive is typically called from an ISR.

This directive will almost certainly cause the calling task to be preempted.

This directive does not generate activity on remote nodes.

25 PCI Library

25.1 Introduction

The Peripheral Component Interconnect (PCI) bus is a very common computer bus architecture that is found in almost every PC today. The PCI bus is normally located at the motherboard where some PCI devices are soldered directly onto the PCB and expansion slots allows the user to add custom devices easily. There is a wide range of PCI hardware available implementing all sorts of interfaces and functions.

This section describes the PCI Library available in RTEMS used to access the PCI bus in a portable way across computer architectures supported by RTEMS.

The PCI Library aims to be compatible with PCI 2.3 with a couple of limitations, for example there is no support for hot-plugging, 64-bit memory space and cardbus bridges.

In order to support different architectures and with small foot-print embedded systems in mind the PCI Library offers four different configuration options listed below. It is selected during compile time by defining the appropriate macros in `confdefs.h`. It is also possible to enable NONE (No Configuration) which can be used for debugging PCI access functions.

- Auto Configuration (do Plug & Play)
- Read Configuration (read BIOS or boot loader configuration)
- Static Configuration (write user defined configuration)
- Peripheral Configuration (no access to `cfg-space`)

25.2 Background

The PCI bus is constructed in a way where on-board devices and devices in expansion slots can be automatically found (probed) and configured using Plug & Play completely implemented in software. The bus is set up once during boot up. The Plug & Play information can be read and written from PCI configuration space. A PCI device is identified in configuration space by a unique bus, slot and function number. Each PCI slot can have up to 8 functions and interface to another PCI sub-bus by implementing a PCI-to-PCI bridge according to the PCI Bridge Architecture specification.

Using the unique `[bus:slot:func]` any device can be configured regardless how PCI is currently set up as long as all PCI buses are enumerated correctly. The enumeration is done during probing, all bridges are given a bus numbers in order for the bridges to respond to accesses from both directions. The PCI library can assign address ranges to which a PCI device should respond using Plug & Play technique or a static user defined configuration. After the configuration has been performed the PCI device drivers can find devices by the read-only PCI Class type, Vendor ID and Device ID information found in configuration space for each device.

In some systems there is a boot loader or BIOS which have already configured all PCI devices, but on embedded targets it is quite common that there is no BIOS or boot loader, thus RTEMS must configure the PCI bus. Only the PCI host may do configuration space access, the host driver or BSP is responsible to translate the `[bus:slot:func]` into a valid PCI configuration space access.

If the target is not a host, but a peripheral, configuration space can not be accessed, the peripheral is set up by the host during start up. In complex embedded PCI systems the peripheral may need to access other PCI boards than then host. In such systems a custom (static) configuration of both the host and peripheral may be a convenient solution.

The PCI bus defines four interrupt signals INTA#..INTD#. The interrupt signals must be mapped into a system interrupt/vector, it is up to the BSP or host driver to know the mapping, however the BIOS or boot loader may use the 8-bit read/write "Interrupt Line" register to pass the knowledge along to the OS.

The PCI standard defines and recommends that the backplane route the interupt lines in a systematic way, however in

25.2.1 Software Components

The PCI library is located in cpukit/libpci, it consists of different parts:

- PCI Host bridge driver interface
- Configuration routines
- Access (Configuration, I/O and Memory space) routines
- Interrupt routines (implemented by BSP)
- Print routines
- Static/peripheral configuration creation
- PCI shell command

25.2.2 PCI Configuration

During start up the PCI bus must be configured in order for host and peripherals to access one another using Memory or I/O accesses and that interrupts are properly handled. Three different spaces are defined and mapped separately:

1. I/O space (IO)
2. non-prefetchable Memory space (MEMIO)
3. prefetchable Memory space (MEM)

Regions of the same type (I/O or Memory) may not overlap which is guaranteed by the software. MEM regions may be mapped into MEMIO regions, but MEMIO regions can not be mapped into MEM, for that could lead to prefetching of registers. The interrupt pin which a board is driving can be read out from PCI configuration space, however it is up to software to know how interrupt signals are routed between PCI-to-PCI bridges and how PCI INT[A..D]# pins are mapped to system IRQ. In systems where previous software (boot loader or BIOS) has already set up this the configuration overwritten or simply read out.

In order to support different configuration methods the following configuration libraries are available can selectable by the user:

- Auto Configuration (run Plug & Play software)
- Read Configuration (relies on a boot loader or BIOS)
- Static Configuration (write user defined setup, no Plug & Play)

- Peripheral Configuration (user defined setup, no access to configuration space)

A host driver can be made to support all three configuration methods, or any combination. It may be defined by the BSP which approach is used.

The configuration software is called from the PCI driver (`pci_config_init()`).

Regardless of configuration method a PCI device tree is created in RAM during initialization, the tree can be accessed to find devices and resources without accessing configuration space later on. The user is responsible to create the device tree at compile time when using the static/peripheral method.

25.2.2.1 RTEMS Configuration selection

The active configuration method can be selected at compile time in the same way as other project parameters by including `rtems/confdefs.h` and setting

- `CONFIGURE_INIT`
- `RTEMS_PCI_CONFIG_LIB`
- `CONFIGURE_PCI_LIB = PCI_LIB_(AUTO,STATIC,READ,PERIPHERAL)`

See the RTEMS configuration section how to setup the PCI library.

25.2.2.2 Auto Configuration

The auto configuration software enumerate PCI buses and initializes all PCI devices found using Plug & Play. The auto configuration software requires that a configuration setup has been registered by the driver or BSP in order to setup the I/O and Memory regions at the correct address ranges. PCI interrupt pins can optionally be routed over PCI-to-PCI bridges and mapped to a system interrupt number. Resources are sorted by size and required alignment, unused "dead" space may be created when PCI bridges are present due to the PCI bridge window size does not equal the alignment, to cope with that resources are reordered to fit smaller BARs into the dead space to minimize the PCI space required. If a BAR or ROM register can not be allocated a PCI address region (due to too few resources available) the register will be given the value of `pci_invalid_address` which defaults to 0.

The auto configuration routines support:

- PCI 2.3
- Little and big endian PCI bus
- one I/O 16 or 32-bit range (IO)
- memory space (MEMIO)
- prefetchable memory space (MEM), if not present MEM will be mapped into MEMIO
- multiple PCI buses - PCI-to-PCI bridges
- standard BARs, PCI-to-PCI bridge BARs, ROM BARs
- Interrupt routing over bridges
- Interrupt pin to system interrupt mapping

Not supported:

- hot-pluggable devices
- Cardbus bridges
- 64-bit memory space
- 16-bit and 32-bit I/O address ranges at the same time

In PCI 2.3 there may exist I/O BARs that must be located at the low 64kBytes address range, in order to support this the host driver or BSP must make sure that I/O addresses region is within this region.

25.2.2.3 Read Configuration

When a BIOS or boot loader already has setup the PCI bus the configuration can be read directly from the PCI resource registers and buses are already enumerated, this is a much simpler approach than configuring PCI ourselves. The PCI device tree is automatically created based on the current configuration and devices present. After initialization is done there is no difference between the auto or read configuration approaches.

25.2.2.4 Static Configuration

To support custom configurations and small-footprint PCI systems, the user may provide the PCI device tree which contains the current configuration. The PCI buses are enumerated and all resources are written to PCI devices during initialization. When this approach is selected PCI boards must be located at the same slots every time and devices can not be removed or added, Plug & Play is not performed. Boards of the same type may of course be exchanged.

The user can create a configuration by calling `pci_cfg_print()` on a running system that has had PCI setup by the auto or read configuration routines, it can be called from the PCI shell command. The user must provide the PCI device tree named `pci_hb`.

25.2.2.5 Peripheral Configuration

On systems where a peripheral PCI device needs to access other PCI devices than the host the peripheral configuration approach may be handy. Most PCI devices answers on the PCI host's requests and start DMA accesses into the Hosts memory, however in some complex systems PCI devices may want to access other devices on the same bus or at another PCI bus.

A PCI peripheral is not allowed to do PCI configuration cycles, which means that it must either rely on the host to give it the addresses it needs, or that the addresses are predefined.

This configuration approach is very similar to the static option, however the configuration is never written to PCI bus, instead it is only used for drivers to find PCI devices and resources using the same PCI API as for the host

25.2.3 PCI Access

The PCI access routines are low-level routines provided for drivers, configuration software, etc. in order to access different regions in a way not dependent upon the host driver, BSP or platform.

- PCI configuration space

- PCI I/O space
- Registers over PCI memory space
- Translate PCI address into CPU accessible address and vice verse

By using the access routines drivers can be made portable over different architectures. The access routines take the architecture endianness into consideration and let the host driver or BSP implement I/O space and configuration space access.

Some non-standard hardware may also define the PCI bus big-endian, for example the LEON2 AT697 PCI host bridge and some LEON3 systems may be configured that way. It is up to the BSP to set the appropriate PCI endianness on compile time (BSP_PCI_BIG_ENDIAN) in order for inline macros to be correctly defined. Another possibility is to use the function pointers defined by the access layer to implement drivers that support "run-time endianness detection".

25.2.3.1 Configuration space

Configuration space is accessed using the routines listed below. The `pci_dev_t` type is used to specify a specific PCI bus, device and function. It is up to the host driver or BSP to create a valid access to the requested PCI slot. Requests made to slots that is not supported by hardware should result in `PCISTS_MSTABRT` and/or data must be ignored (writes) or `0xffffffff` is always returned (reads).

```
/* Configuration Space Access Read Routines */
extern int pci_cfg_r8(pci_dev_t dev, int ofs, uint8_t *data);
extern int pci_cfg_r16(pci_dev_t dev, int ofs, uint16_t *data);
extern int pci_cfg_r32(pci_dev_t dev, int ofs, uint32_t *data);

/* Configuration Space Access Write Routines */
extern int pci_cfg_w8(pci_dev_t dev, int ofs, uint8_t data);
extern int pci_cfg_w16(pci_dev_t dev, int ofs, uint16_t data);
extern int pci_cfg_w32(pci_dev_t dev, int ofs, uint32_t data);
```

25.2.3.2 I/O space

The BSP or driver provide special routines in order to access I/O space. Some architectures have a special instruction accessing I/O space, others have it mapped into a "PCI I/O window" in the standard address space accessed by the CPU. The window size may vary and must be taken into consideration by the host driver. The below routines must be used to access I/O space. The address given to the functions is not the PCI I/O addresses, the caller must have translated PCI I/O addresses (available in the PCI BARs) into a BSP or host driver custom address, see Access functions how addresses are translated.

```
/* Read a register over PCI I/O Space */
extern uint8_t pci_io_r8(uint32_t adr);
extern uint16_t pci_io_r16(uint32_t adr);
extern uint32_t pci_io_r32(uint32_t adr);

/* Write a register over PCI I/O Space */
extern void pci_io_w8(uint32_t adr, uint8_t data);
```

```
extern void pci_io_w16(uint32_t adr, uint16_t data);
extern void pci_io_w32(uint32_t adr, uint32_t data);
```

25.2.3.3 Registers over Memory space

PCI host bridge hardware normally swap data accesses into the endianness of the host architecture in order to lower the load of the CPU, peripherals can do DMA without swapping. However, the host controller can not separate a standard memory access from a memory access to a register, registers may be mapped into memory space. This leads to register content being swapped, which must be swapped back. The below routines makes it possible to access registers over PCI memory space in a portable way on different architectures, the BSP or architecture must provide necessary functions in order to implement this.

```
static inline uint16_t pci_ld_le16(volatile uint16_t *addr);
static inline void pci_st_le16(volatile uint16_t *addr, uint16_t val);
static inline uint32_t pci_ld_le32(volatile uint32_t *addr);
static inline void pci_st_le32(volatile uint32_t *addr, uint32_t val);
static inline uint16_t pci_ld_be16(volatile uint16_t *addr);
static inline void pci_st_be16(volatile uint16_t *addr, uint16_t val);
static inline uint32_t pci_ld_be32(volatile uint32_t *addr);
static inline void pci_st_be32(volatile uint32_t *addr, uint32_t val);
```

In order to support non-standard big-endian PCI bus the above pci_* functions is required, pci_ld_le16 != ld_le16 on big endian PCI buses.

25.2.3.4 Access functions

The PCI Access Library can provide device drivers with function pointers executing the above Configuration, I/O and Memory space accesses. The functions have the same arguments and return values as the as the above functions.

The pci_access_func() function defined below can be used to get a function pointer of a specific access type.

```
/* Get Read/Write function for accessing a register over PCI Memory Space
 * (non-inline functions).
 *
 * Arguments
 *   wr          0(Read), 1(Write)
 *   size        1(Byte), 2(Word), 4(Double Word)
 *   func        Where function pointer will be stored
 *   endian      PCI_LITTLE_ENDIAN or PCI_BIG_ENDIAN
 *   type        1(I/O), 3(REG over MEM), 4(CFG)
 *
 * Return
 *   0           Found function
 *   others      No such function defined by host driver or BSP
 */
int pci_access_func(int wr, int size, void **func, int endian, int type);
```

PCI devices drivers may be written to support run-time detection of endianness, this is mosly for debugging or for development systems. When the product is finally deployed macros switch to using the inline functions instead which have been configured for the correct endianness.

25.2.3.5 PCI address translation

When PCI addresses, both I/O and memory space, is not mapped 1:1 address translation before access is needed. If drivers read the PCI resources directly using configuration space routines or in the device tree, the addresses given are PCI addresses. The below functions can be used to translate PCI addresses into CPU accessible addresses or vise versa, translation may be different for different PCI spaces/regions.

```
/* Translate PCI address into CPU accessible address */
static inline int pci_pci2cpu(uint32_t *address, int type);

/* Translate CPU accessible address into PCI address (for DMA) */
static inline int pci_cpu2pci(uint32_t *address, int type);
```

25.2.4 PCI Interrupt

The PCI specification defines four different interrupt lines INTA#..INTD#, the interrupts are low level sensitive which make it possible to support multiple interrupt sources on the same interrupt line. Since the lines are level sensitive the interrupt sources must be acknowledged before clearing the interrupt controller, or the interrupt controller must be masked. The BSP must provide a routine for clearing/acknowledging the interrupt controller, it is up to the interrupt service routine to acknowledge the interrupt source.

The PCI Library relies on the BSP for implementing shared interrupt handling through the BSP_PCI_shared_interrupt_* functions/macros, they must be defined when including bsp.h.

PCI device drivers may use the pci_interrupt_ routines in order to call the BSP specific functions in a platform independent way. The PCI interrupt interface has been made similar to the RTEMS IRQ extension so that a BSP can use the standard RTEMS interrupt functions directly.

25.2.5 PCI Shell command

The RTEMS shell have a PCI command 'pci' which makes it possible to read/write configuration space, print the current PCI configuration and print out a configuration C-file for the static or peripheral library.

26 Stack Bounds Checker

26.1 Introduction

The stack bounds checker is an RTEMS support component that determines if a task has overrun its run-time stack. The routines provided by the stack bounds checker manager are:

- `rtems_stack_checker_is_blow`n - Has the Current Task Blown its Stack
- `rtems_stack_checker_report_usage` - Report Task Stack Usage

26.2 Background

26.2.1 Task Stack

Each task in a system has a fixed size stack associated with it. This stack is allocated when the task is created. As the task executes, the stack is used to contain parameters, return addresses, saved registers, and local variables. The amount of stack space required by a task is dependent on the exact set of routines used. The peak stack usage reflects the worst case of subroutine pushing information on the stack. For example, if a subroutine allocates a local buffer of 1024 bytes, then this data must be accounted for in the stack of every task that invokes that routine.

Recursive routines make calculating peak stack usage difficult, if not impossible. Each call to the recursive routine consumes n bytes of stack space. If the routine recursives 1000 times, then $1000 * n$ bytes of stack space are required.

26.2.2 Execution

The stack bounds checker operates as a set of task extensions. At task creation time, the task's stack is filled with a pattern to indicate the stack is unused. As the task executes, it will overwrite this pattern in memory. At each task switch, the stack bounds checker's task switch extension is executed. This extension checks that:

- the last n bytes of the task's stack have not been overwritten. If this pattern has been damaged, it indicates that at some point since this task was context switch to the CPU, it has used too much stack space.
- the current stack pointer of the task is not within the address range allocated for use as the task's stack.

If either of these conditions is detected, then a blown stack error is reported using the `printk` routine.

The number of bytes checked for an overwrite is processor family dependent. The minimum stack frame per subroutine call varies widely between processor families. On CISC families like the Motorola MC68xxx and Intel ix86, all that is needed is a return address. On more complex RISC processors, the minimum stack frame per subroutine call may include space to save a significant number of registers.

Another processor dependent feature that must be taken into account by the stack bounds checker is the direction that the stack grows. On some processor families, the stack grows

up or to higher addresses as the task executes. On other families, it grows down to lower addresses. The stack bounds checker implementation uses the stack description definitions provided by every RTEMS port to get for this information.

26.3 Operations

26.3.1 Initializing the Stack Bounds Checker

The stack checker is initialized automatically when its task create extension runs for the first time.

The application must include the stack bounds checker extension set in its set of Initial Extensions. This set of extensions is defined as `STACK_CHECKER_EXTENSION`. If using `<rtems/confdefs.h>` for Configuration Table generation, then all that is necessary is to define the macro `CONFIGURE_STACK_CHECKER_ENABLED` before including `<rtems/confdefs.h>` as shown below:

```
#define CONFIGURE_STACK_CHECKER_ENABLED
...
#include <rtems/confdefs.h>
```

26.3.2 Checking for Blown Task Stack

The application may check whether the stack pointer of currently executing task is within proper bounds at any time by calling the `rtems_stack_checker_is_blown` method. This method return `FALSE` if the task is operating within its stack bounds and has not damaged its pattern area.

26.3.3 Reporting Task Stack Usage

The application may dynamically report the stack usage for every task in the system by calling the `rtems_stack_checker_report_usage` routine. This routine prints a table with the peak usage and stack size of every task in the system. The following is an example of the report generated:

ID	NAME	LOW	HIGH	AVAILABLE	USED
0x04010001	IDLE	0x003e8a60	0x003e9667	2952	200
0x08010002	TA1	0x003e5750	0x003e7b57	9096	1168
0x08010003	TA2	0x003e31c8	0x003e55cf	9096	1168
0x08010004	TA3	0x003e0c40	0x003e3047	9096	1104
0xffffffff	INTR	0x003ecfc0	0x003effbf	12160	128

Notice the last time. The task id is 0xffffffff and its name is "INTR". This is not actually a task, it is the interrupt stack.

26.3.4 When a Task Overflows the Stack

When the stack bounds checker determines that a stack overflow has occurred, it will attempt to print a message using `printk` identifying the task and then shut the system down. If the stack overflow has caused corruption, then it is possible that the message can not be printed.

The following is an example of the output generated:

```
BLOWN STACK!!! Offending task(0x3eb360): id=0x08010002; name=0x54413120
stack covers range 0x003e5750 - 0x003e7b57 (9224 bytes)
Damaged pattern begins at 0x003e5758 and is 128 bytes long
```

The above includes the task id and a pointer to the task control block as well as enough information so one can look at the task's stack and see what was happening.

26.4 Routines

This section details the stack bounds checker's routines. A subsection is dedicated to each of routines and describes the calling sequence, related constants, usage, and status codes.

26.4.1 STACK_CHECKER_IS_BLOWN - Has Current Task Blown Its Stack

CALLING SEQUENCE:

```
bool rtems_stack_checker_is_blownd( void );
```

STATUS CODES:

TRUE - Stack is operating within its stack limits

FALSE - Current stack pointer is outside allocated area

DESCRIPTION:

This method is used to determine if the current stack pointer of the currently executing task is within bounds.

NOTES:

This method checks the current stack pointer against the high and low addresses of the stack memory allocated when the task was created and it looks for damage to the high water mark pattern for the worst case usage of the task being called.

26.4.2 STACK_CHECKER_REPORT_USAGE - Report Task Stack Usage

CALLING SEQUENCE:

```
void rtems_stack_checker_report_usage( void );
```

STATUS CODES: NONE

DESCRIPTION:

This routine prints a table with the peak stack usage and stack space allocation of every task in the system.

NOTES:

NONE

27 CPU Usage Statistics

27.1 Introduction

The CPU usage statistics manager is an RTEMS support component that provides a convenient way to manipulate the CPU usage information associated with each task. The routines provided by the CPU usage statistics manager are:

- `rtems_cpu_usage_report` - Report CPU Usage Statistics
- `rtems_cpu_usage_reset` - Reset CPU Usage Statistics

27.2 Background

When analyzing and debugging real-time applications, it is important to be able to know how much CPU time each task in the system consumes. This support component provides a mechanism to easily obtain this information with little burden placed on the target.

The raw data is gathered as part of performing a context switch. RTEMS keeps track of how many clock ticks have occurred while the task being switched out has been executing. If the task has been running less than 1 clock tick, then for the purposes of the statistics, it is assumed to have executed 1 clock tick. This results in some inaccuracy but the alternative is for the task to have appeared to execute 0 clock ticks.

RTEMS versions newer than the 4.7 release series, support the ability to obtain timestamps with nanosecond granularity if the BSP provides support. It is a desirable enhancement to change the way the usage data is gathered to take advantage of this recently added capability. Please consider sponsoring the core RTEMS development team to add this capability.

27.3 Operations

27.3.1 Report CPU Usage Statistics

The application may dynamically report the CPU usage for every task in the system by calling the `rtems_cpu_usage_report` routine. This routine prints a table with the following information per task:

- task id
- task name
- number of clock ticks executed
- percentage of time consumed by this task

The following is an example of the report generated:

CPU USAGE BY THREAD			
ID	NAME	SECONDS	PERCENT
0x04010001	IDLE	0	0.000
0x08010002	TA1	1203	0.748
0x08010003	TA2	203	0.126
0x08010004	TA3	202	0.126
TICKS SINCE LAST SYSTEM RESET:			1600
TOTAL UNITS:			1608

Notice that the "TOTAL UNITS" is greater than the ticks per reset. This is an artifact of the way in which RTEMS keeps track of CPU usage. When a task is context switched into the CPU, the number of clock ticks it has executed is incremented. While the task is executing, this number is incremented on each clock tick. Otherwise, if a task begins and completes execution between successive clock ticks, there would be no way to tell that it executed at all.

Another thing to keep in mind when looking at idle time, is that many systems – especially during debug – have a task providing some type of debug interface. It is usually fine to think of the total idle time as being the sum of the IDLE task and a debug task that will not be included in a production build of an application.

27.3.2 Reset CPU Usage Statistics

Invoking the `rtems_cpu_usage_reset` routine resets the CPU usage statistics for all tasks in the system.

27.4 Directives

This section details the CPU usage statistics manager's directives. A subsection is dedicated to each of this manager's directives and describes the calling sequence, related constants, usage, and status codes.

27.4.1 cpu_usage_report - Report CPU Usage Statistics

CALLING SEQUENCE:

```
void rtems_cpu_usage_report( void );
```

STATUS CODES: NONE

DESCRIPTION:

This routine prints out a table detailing the CPU usage statistics for all tasks in the system.

NOTES:

The table is printed using the `printk` routine.

27.4.2 cpu_usage_reset - Reset CPU Usage Statistics

CALLING SEQUENCE:

```
void rtems_cpu_usage_reset( void );
```

STATUS CODES: NONE

DESCRIPTION:

This routine re-initializes the CPU usage statistics for all tasks in the system to their initial state. The initial state is that a task has not executed and thus has consumed no CPU time. default state which is when zero period executions have occurred.

NOTES:

NONE

28 Object Services

28.1 Introduction

RTEMS provides a collection of services to assist in the management and usage of the objects created and utilized via other managers. These services assist in the manipulation of RTEMS objects independent of the API used to create them. The object related services provided by RTEMS are:

- `rtems_build_name` - build object name from characters
- `rtems_object_get_classic_name` - lookup name from Id
- `rtems_object_get_name` - obtain object name as string
- `rtems_object_set_name` - set object name
- `rtems_object_id_get_api` - obtain API from Id
- `rtems_object_id_get_class` - obtain class from Id
- `rtems_object_id_get_node` - obtain node from Id
- `rtems_object_id_get_index` - obtain index from Id
- `rtems_build_id` - build object id from components
- `rtems_object_id_api_minimum` - obtain minimum API value
- `rtems_object_id_api_maximum` - obtain maximum API value
- `rtems_object_id_api_minimum_class` - obtain minimum class value
- `rtems_object_id_api_maximum_class` - obtain maximum class value
- `rtems_object_get_api_name` - obtain API name
- `rtems_object_get_api_class_name` - obtain class name
- `rtems_object_get_class_information` - obtain class information

28.2 Background

28.2.1 APIs

RTEMS implements multiple APIs including an Internal API, the Classic API, the POSIX API, and the uITRON API. These APIs share the common foundation of SuperCore objects and thus share object management code. This includes a common scheme for object Ids and for managing object names whether those names be in the thirty-two bit form used by the Classic API or C strings.

The object Id contains a field indicating the API that an object instance is associated with. This field holds a numerically small non-zero integer.

28.2.2 Object Classes

Each API consists of a collection of managers. Each manager is responsible for instances of a particular object class. Classic API Tasks and POSIX Mutexes example classes.

The object Id contains a field indicating the class that an object instance is associated with. This field holds a numerically small non-zero integer. In all APIs, a class value of one is reserved for tasks or threads.

28.2.3 Object Names

Every RTEMS object which has an Id may also have a name associated with it. Depending on the API, names may be either thirty-two bit integers as in the Classic API or strings as in the POSIX API.

Some objects have Ids but do not have a defined way to associate a name with them. For example, POSIX threads have Ids but per POSIX do not have names. In RTEMS, objects not defined to have thirty-two bit names may have string names assigned to them via the `rtems_object_set_name` service. The original impetus in providing this service was so the normally anonymous POSIX threads could have a user defined name in CPU Usage Reports.

28.3 Operations

28.3.1 Decomposing and Recomposing an Object Id

Services are provided to decompose an object Id into its subordinate components. The following services are used to do this:

- `rtems_object_id_get_api`
- `rtems_object_id_get_class`
- `rtems_object_id_get_node`
- `rtems_object_id_get_index`

The following C language example illustrates the decomposition of an Id and printing the values.

```
void printObjectId(rtems_id id)
{
    printf(
        "API=%d Class=%d Node=%d Index=%d\n",
        rtems_object_id_get_api(id),
        rtems_object_id_get_class(id),
        rtems_object_id_get_node(id),
        rtems_object_id_get_index(id)
    );
}
```

This prints the components of the Ids as integers.

It is also possible to construct an arbitrary Id using the `rtems_build_id` service. The following C language example illustrates how to construct the "next Id."

```
rtems_id nextObjectId(rtems_id id)
{
    return rtems_build_id(
        rtems_object_id_get_api(id),
        rtems_object_id_get_class(id),
        rtems_object_id_get_node(id),
        rtems_object_id_get_index(id) + 1
    );
}
```

```
    );  
}
```

Note that this Id may not be valid in this system or associated with an allocated object.

28.3.2 Printing an Object Id

RTEMS also provides services to associate the API and Class portions of an Object Id with strings. This allows the application developer to provide more information about an object in diagnostic messages.

In the following C language example, an Id is decomposed into its constituent parts and "pretty-printed."

```
void prettyPrintObjectId(rtems_id id)  
{  
    int tmpAPI, tmpClass;  
  
    tmpAPI    = rtems_object_id_get_api(id),  
    tmpClass  = rtems_object_id_get_class(id),  
  
    printf(  
        "API=%s Class=%s Node=%d Index=%d\n",  
        rtems_object_get_api_name(tmpAPI),  
        rtems_object_get_api_class_name(tmpAPI, tmpClass),  
        rtems_object_id_get_node(id),  
        rtems_object_id_get_index(id)  
    );  
}
```

28.4 Directives

28.4.1 BUILD_NAME - Build object name from characters

CALLING SEQUENCE:

```
rtems_name rtems_build_name(  
    uint8_t c1,  
    uint8_t c2,  
    uint8_t c3,  
    uint8_t c4  
);
```

DIRECTIVE STATUS CODES

Returns a name constructed from the four characters.

DESCRIPTION:

This service takes the four characters provided as arguments and constructs a thirty-two bit object name with `c1` in the most significant byte and `c4` in the least significant byte.

NOTES:

This directive is strictly local and does not impact task scheduling.

28.4.2 OBJECT_GET_CLASSIC_NAME - Lookup name from id

CALLING SEQUENCE:

```
rtcms_status_code rtcms_object_get_classic_name(  
    rtcms_id      id,  
    rtcms_name    *name  
);
```

DIRECTIVE STATUS CODES

RTEMS_SUCCESSFUL - name looked up successfully

RTEMS_INVALID_ADDRESS - invalid name pointer

RTEMS_INVALID_ID - invalid object id

DESCRIPTION:

This service looks up the name for the object `id` specified and, if found, places the result in `*name`.

NOTES:

This directive is strictly local and does not impact task scheduling.

28.4.3 OBJECT_GET_NAME - Obtain object name as string

CALLING SEQUENCE:

```
char *rtems_object_get_name(  
    rtems_id      id,  
    size_t        length,  
    char          *name  
);
```

DIRECTIVE STATUS CODES

Returns a pointer to the name if successful or NULL otherwise.

DESCRIPTION:

This service looks up the name of the object specified by `id` and places it in the memory pointed to by `name`. Every attempt is made to return name as a printable string even if the object has the Classic API thirty-two bit style name.

NOTES:

This directive is strictly local and does not impact task scheduling.

28.4.4 OBJECT_SET_NAME - Set object name

CALLING SEQUENCE:

```
rtcms_status_code rtcms_object_set_name(  
    rtcms_id      id,  
    const char    *name  
);
```

DIRECTIVE STATUS CODES

RTEMS_SUCCESSFUL - name looked up successfully

RTEMS_INVALID_ADDRESS - invalid name pointer

RTEMS_INVALID_ID - invalid object id

DESCRIPTION:

This service sets the name of **id** to that specified by the string located at **name**.

NOTES:

This directive is strictly local and does not impact task scheduling.

If the object specified by **id** is of a class that has a string name, this method will free the existing name to the RTEMS Workspace and allocate enough memory from the RTEMS Workspace to make a copy of the string located at **name**.

If the object specified by **id** is of a class that has a thirty-two bit integer style name, then the first four characters in ***name** will be used to construct the name. name to the RTEMS Workspace and allocate enough memory from the RTEMS Workspace to make a copy of the string

28.4.5 OBJECT_ID_GET_API - Obtain API from Id

CALLING SEQUENCE:

```
int rtems_object_id_get_api(  
    rtems_id id  
);
```

DIRECTIVE STATUS CODES

Returns the API portion of the object Id.

DESCRIPTION:

This directive returns the API portion of the provided object id.

NOTES:

This directive is strictly local and does not impact task scheduling.

This directive does NOT validate the id provided.

28.4.6 OBJECT_ID_GET_CLASS - Obtain Class from Id

CALLING SEQUENCE:

```
int rtems_object_id_get_class(  
    rtems_id id  
);
```

DIRECTIVE STATUS CODES

Returns the class portion of the object Id.

DESCRIPTION:

This directive returns the class portion of the provided object id.

NOTES:

This directive is strictly local and does not impact task scheduling.

This directive does NOT validate the id provided.

28.4.7 OBJECT_ID_GET_NODE - Obtain Node from Id

CALLING SEQUENCE:

```
int rtems_object_id_get_node(  
    rtems_id id  
);
```

DIRECTIVE STATUS CODES

Returns the node portion of the object Id.

DESCRIPTION:

This directive returns the node portion of the provided object id.

NOTES:

This directive is strictly local and does not impact task scheduling.

This directive does NOT validate the id provided.

28.4.8 OBJECT_ID_GET_INDEX - Obtain Index from Id

CALLING SEQUENCE:

```
int rtems_object_id_get_index(  
    rtems_id id  
);
```

DIRECTIVE STATUS CODES

Returns the index portion of the object Id.

DESCRIPTION:

This directive returns the index portion of the provided object `id`.

NOTES:

This directive is strictly local and does not impact task scheduling.

This directive does NOT validate the `id` provided.

28.4.9 BUILD_ID - Build Object Id From Components

CALLING SEQUENCE:

```
rtcms_id rtcms_build_id(  
    int the_api,  
    int the_class,  
    int the_node,  
    int the_index  
);
```

DIRECTIVE STATUS CODES

Returns an object Id constructed from the provided arguments.

DESCRIPTION:

This service constructs an object Id from the provided `the_api`, `the_class`, `the_node`, and `the_index`.

NOTES:

This directive is strictly local and does not impact task scheduling.

This directive does NOT validate the arguments provided or the Object id returned.

28.4.10 OBJECT_ID_API_MINIMUM - Obtain Minimum API Value

CALLING SEQUENCE:

```
int rtems_object_id_api_minimum(void);
```

DIRECTIVE STATUS CODES

Returns the minimum valid for the API portion of an object Id.

DESCRIPTION:

This service returns the minimum valid for the API portion of an object Id.

NOTES:

This directive is strictly local and does not impact task scheduling.

28.4.11 OBJECT_ID_API_MAXIMUM - Obtain Maximum API Value

CALLING SEQUENCE:

```
int rtems_object_id_api_maximum(void);
```

DIRECTIVE STATUS CODES

Returns the maximum valid for the API portion of an object Id.

DESCRIPTION:

This service returns the maximum valid for the API portion of an object Id.

NOTES:

This directive is strictly local and does not impact task scheduling.

28.4.12 OBJECT_API_MINIMUM_CLASS - Obtain Minimum Class Value

CALLING SEQUENCE:

```
int rtems_object_api_minimum_class(  
    int api  
);
```

DIRECTIVE STATUS CODES

If `api` is not valid, -1 is returned.

If successful, this service returns the minimum valid for the class portion of an object Id for the specified `api`.

DESCRIPTION:

This service returns the minimum valid for the class portion of an object Id for the specified `api`.

NOTES:

This directive is strictly local and does not impact task scheduling.

28.4.13 OBJECT_API_MAXIMUM_CLASS - Obtain Maximum Class Value

CALLING SEQUENCE:

```
int rtems_object_api_maximum_class(  
    int api  
);
```

DIRECTIVE STATUS CODES

If `api` is not valid, -1 is returned.

If successful, this service returns the maximum valid for the class portion of an object Id for the specified `api`.

DESCRIPTION:

This service returns the maximum valid for the class portion of an object Id for the specified `api`.

NOTES:

This directive is strictly local and does not impact task scheduling.

28.4.14 OBJECT_GET_API_NAME - Obtain API Name

CALLING SEQUENCE:

```
const char *rtems_object_get_api_name(  
    int api  
);
```

DIRECTIVE STATUS CODES

If `api` is not valid, the string "BAD API" is returned.

If successful, this service returns a pointer to a string containing the name of the specified `api`.

DESCRIPTION:

This service returns the name of the specified `api`.

NOTES:

This directive is strictly local and does not impact task scheduling.

The string returned is from constant space. Do not modify or free it.

28.4.15 OBJECT_GET_API_CLASS_NAME - Obtain Class Name

CALLING SEQUENCE:

```
const char *rtems_object_get_api_class_name(  
    int the_api,  
    int the_class  
);
```

DIRECTIVE STATUS CODES

If `the_api` is not valid, the string "BAD API" is returned.

If `the_class` is not valid, the string "BAD CLASS" is returned.

If successful, this service returns a pointer to a string containing the name of the specified `the_api/the_class` pair.

DESCRIPTION:

This service returns the name of the object class indicated by the specified `the_api` and `the_class`.

NOTES:

This directive is strictly local and does not impact task scheduling.

The string returned is from constant space. Do not modify or free it.

28.4.16 OBJECT_GET_CLASS_INFORMATION - Obtain Class Information

CALLING SEQUENCE:

```
rtems_status_code rtems_object_get_class_information(  
    int                the_api,  
    int                the_class,  
    rtems_object_api_class_information *info  
);
```

DIRECTIVE STATUS CODES

RTEMS_SUCCESSFUL - information obtained successfully

RTEMS_INVALID_ADDRESS - `info` is NULL

RTEMS_INVALID_NUMBER - invalid `api` or `the_class`

If successful, the structure located at `info` will be filled in with information about the specified `api/the_class` pairing.

DESCRIPTION:

This service returns information about the object class indicated by the specified `api` and `the_class`. This structure is defined as follows:

```
typedef struct {  
    rtems_id  minimum_id;  
    rtems_id  maximum_id;  
    int       maximum;  
    bool      auto_extend;  
    int       unallocated;  
} rtems_object_api_class_information;
```

NOTES:

This directive is strictly local and does not impact task scheduling.

29 Chains

29.1 Introduction

The Chains API is an interface to the Super Core (score) chain implementation. The Super Core uses chains for all list type functions. This includes wait queues and task queues. The Chains API provided by RTEMS is:

- `rtems_chain_node` - Chain node used in user objects
- `rtems_chain_control` - Chain control node
- `rtems_chain_initialize` - initialize the chain with nodes
- `rtems_chain_initialize_empty` - initialize the chain as empty
- `rtems_chain_is_null_node` - Is the node NULL ?
- `rtems_chain_head` - Return the chain's head
- `rtems_chain_tail` - Return the chain's tail
- `rtems_chain_are_nodes_equal` - Are the node's equal ?
- `rtems_chain_is_empty` - Is the chain empty ?
- `rtems_chain_is_first` - Is the Node the first in the chain ?
- `rtems_chain_is_last` - Is the Node the last in the chain ?
- `rtems_chain_has_only_one_node` - Does the node have one node ?
- `rtems_chain_is_head` - Is the node the head ?
- `rtems_chain_is_tail` - Is the node the tail ?
- `rtems_chain_extract` - Extract the node from the chain
- `rtems_chain_extract_unprotected` - Extract the node from the chain (unprotected)
- `rtems_chain_get` - Return the first node on the chain
- `rtems_chain_get_unprotected` - Return the first node on the chain (unprotected)
- `rtems_chain_insert` - Insert the node into the chain
- `rtems_chain_insert_unprotected` - Insert the node into the chain (unprotected)
- `rtems_chain_append` - Append the node to chain
- `rtems_chain_append_unprotected` - Append the node to chain (unprotected)
- `rtems_chain_prepend` - Prepend the node to the end of the chain
- `rtems_chain_prepend_unprotected` - Prepend the node to chain (unprotected)

29.2 Background

The Chains API maps to the Super Core Chains API. Chains are implemented as a double linked list of nodes anchored to a control node. The list starts at the control node and is terminated at the control node. A node has previous and next pointers. Being a double linked list nodes can be inserted and removed without the need to traverse the chain.

Chains have a small memory footprint and can be used in interrupt service routines and are thread safe in a multi-threaded environment. The directives list which operations disable interrupts.

Chains are very useful in Board Support packages and applications.

29.2.1 Nodes

A chain is made up from nodes that originate from a chain control object. A node is of type `rtems_chain_node`. The node is designed to be part of a user data structure and a cast is used to move from the node address to the user data structure address. For example:

```
typedef struct foo
{
    rtems_chain_node node;
    int              bar;
} foo;
```

creates a type `foo` that can be placed on a chain. To get the `foo` structure from the list you perform the following:

```
foo* get_foo(rtems_chain_control* control)
{
    return (foo*) rtems_chain_get(control);
}
```

The node is placed at the start of the user's structure to allow the node address on the chain to be easily cast to the user's structure address.

29.2.2 Controls

A chain is anchored with a control object. Chain control provide the user with access to the nodes on the chain. The control is head of the node.

```
Control
first ----->
permanent_null <----- NODE
last ----->
```

The implementation does not require special checks for manipulating the first and last nodes on the chain. To accomplish this the `rtems_chain_control` structure is treated as two overlapping `rtems_chain_node` structures. The permanent head of the chain overlays a node structure on the first and `permanent_null` fields. The `permanent_tail` of the chain overlays a node structure on the `permanent_null` and `last` elements of the structure.

29.3 Operations

29.3.1 Multi-threading

Chains are designed to be used in a multi-threading environment. The directives list which operations mask interrupts. Chains supports tasks and interrupt service routines appending and extracting nodes with out the need for extra locks. Chains how-ever cannot insure the integrity of a chain for all operations. This is the responsibility of the user. For example an interrupt service routine extracting nodes while a task is iterating over the chain can have unpredictable results.

29.3.2 Creating a Chain

To create a chain you need to declare a chain control then add nodes to the control. Consider a user structure and chain control:

```
typedef struct foo
{
    rtems_chain_node node;
    uint8_t char*    data;
} foo;

rtems_chain_control chain;
```

Add nodes with the following code:

```
rtems_chain_initialize_empty (&chain);

for (i = 0; i < count; i++)
{
    foo* bar = malloc (sizeof (foo));
    if (!bar)
        return -1;
    bar->data = malloc (size);
    rtems_chain_append (&chain, &bar->node);
}
```

The chain is initialized and the nodes allocated and appended to the chain. This is an example of a pool of buffers.

29.3.3 Iterating a Chain

Iterating a chain is a common function. The example shows how to iterate the buffer pool chain created in the last section to find buffers starting with a specific string. If the buffer is located it is extracted from the chain and placed on another chain:

```
void foobar (const char*      match,
             rtems_chain_control* chain,
             rtems_chain_control* out)
{
    rtems_chain_node* node;
    foo*              bar;

    rtems_chain_initialize_empty (out);

    node = chain->first;

    while (!rtems_chain_is_tail (chain, node))
    {
        bar = (foo*) node;
        rtems_chain_node* next_node = node->next;
```

```
    if (strcmp (match, bar->data) == 0)
    {
        rtems_chain_extract (node);
        rtems_chain_append (out, node);
    }

    node = next_node;
}
}
```

29.4 Directives

The section details the Chains directives.

29.4.1 Initialize Chain With Nodes

CALLING SEQUENCE:

```
void rtems_chain_initialize(  
    rtems_chain_control *the_chain,  
    void                *starting_address,  
    size_t              number_nodes,  
    size_t              node_size  
)
```

RETURNS

Returns nothing.

DESCRIPTION:

This function take in a pointer to a chain control and initializes it to contain a set of chain nodes. The chain will contain **number_nodes** chain nodes from the memory pointed to by **start_address**. Each node is assumed to be **node_size** bytes.

NOTES:

This call will discard any nodes on the chain.

This call does NOT initialize any user data on each node.

29.4.2 Initialize Empty

CALLING SEQUENCE:

```
void rtems_chain_initialize_empty(  
    rtems_chain_control *the_chain  
);
```

RETURNS

Returns nothing.

DESCRIPTION:

This function take in a pointer to a chain control and initializes it to empty.

NOTES:

This call will discard any nodes on the chain.

29.4.3 Is Null Node ?

CALLING SEQUENCE:

```
bool rtems_chain_is_null_node(  
    const rtems_chain_node *the_node  
);
```

RETURNS

Returns **true** if the node point is **NULL** and **false** if the node is not **NULL**.

DESCRIPTION:

Tests the node to see if it is a **NULL** returning **true** if a null.

29.4.4 Head

CALLING SEQUENCE:

```
    rtems_chain_node *rtems_chain_head(  
        rtems_chain_control *the_chain  
    )
```

RETURNS

Returns the permanent head node of the chain.

DESCRIPTION:

This function returns a pointer to the first node on the chain.

29.4.5 Tail

CALLING SEQUENCE:

```
    rtems_chain_node *rtems_chain_tail(  
        rtems_chain_control *the_chain  
    );
```

RETURNS

Returns the permanent tail node of the chain.

DESCRIPTION:

This function returns a pointer to the last node on the chain.

29.4.6 Are Two Nodes Equal ?

CALLING SEQUENCE:

```
bool rtems_chain_are_nodes_equal(  
    const rtems_chain_node *left,  
    const rtems_chain_node *right  
);
```

RETURNS

This function returns **true** if the left node and the right node are equal, and **false** otherwise.

DESCRIPTION:

This function returns **true** if the left node and the right node are equal, and **false** otherwise.

29.4.7 Is the Chain Empty

CALLING SEQUENCE:

```
bool rtems_chain_is_empty(  
    rtems_chain_control *the_chain  
);
```

RETURNS

This function returns **true** if there are no nodes on the chain and **false** otherwise.

DESCRIPTION:

This function returns **true** if there are no nodes on the chain and **false** otherwise.

29.4.8 Is this the First Node on the Chain ?

CALLING SEQUENCE:

```
bool rtems_chain_is_first(  
    const rtems_chain_node *the_node  
);
```

RETURNS

This function returns **true** if the node is the first node on a chain and **false** otherwise.

DESCRIPTION:

This function returns **true** if the node is the first node on a chain and **false** otherwise.

29.4.9 Is this the Last Node on the Chain ?

CALLING SEQUENCE:

```
bool rtems_chain_is_last(  
    const rtems_chain_node *the_node  
);
```

RETURNS

This function returns **true** if the node is the last node on a chain and **false** otherwise.

DESCRIPTION:

This function returns **true** if the node is the last node on a chain and **false** otherwise.

29.4.10 Does this Chain have only One Node ?

CALLING SEQUENCE:

```
bool rtems_chain_has_only_one_node(  
    const rtems_chain_control *the_chain  
);
```

RETURNS

This function returns **true** if there is only one node on the chain and **false** otherwise.

DESCRIPTION:

This function returns **true** if there is only one node on the chain and **false** otherwise.

29.4.11 Is this Node the Chain Head ?

CALLING SEQUENCE:

```
bool rtems_chain_is_head(  
    rtems_chain_control    *the_chain,  
    rtems_const chain_node *the_node  
);
```

RETURNS

This function returns **true** if the node is the head of the chain and **false** otherwise.

DESCRIPTION:

This function returns **true** if the node is the head of the chain and **false** otherwise.

29.4.12 Is this Node the Chain Tail ?

CALLING SEQUENCE:

```
bool rtems_chain_is_tail(  
    rtems_chain_control *the_chain,  
    const rtems_chain_node *the_node  
)
```

RETURNS

This function returns **true** if the node is the tail of the chain and **false** otherwise.

DESCRIPTION:

This function returns **true** if the node is the tail of the chain and **false** otherwise.

29.4.13 Extract a Node

CALLING SEQUENCE:

```
void rtems_chain_extract(  
    rtems_chain_node *the_node  
);
```

RETURNS

Returns nothing.

DESCRIPTION:

This routine extracts the node from the chain on which it resides.

NOTES:

Interrupts are disabled while extracting the node to ensure the atomicity of the operation.

Use `rtems_chain_extract_unprotected()` to avoid disabling of interrupts.

29.4.14 Get the First Node

CALLING SEQUENCE:

```
rtcms_chain_node *rtcms_chain_get(  
    rtcms_chain_control *the_chain  
);
```

RETURNS

Returns a pointer a node. If a node was removed, then a pointer to that node is returned. If the chain was empty, then NULL is returned.

DESCRIPTION:

This function removes the first node from the chain and returns a pointer to that node. If the chain is empty, then NULL is returned.

NOTES:

Interrupts are disabled while obtaining the node to ensure the atomicity of the operation.

Use `rtcms_chain_get_unprotected()` to avoid disabling of interrupts.

29.4.15 Insert a Node

CALLING SEQUENCE:

```
void rtems_chain_insert(  
    rtems_chain_node *after_node,  
    rtems_chain_node *the_node  
);
```

RETURNS

Returns nothing.

DESCRIPTION:

This routine inserts a node on a chain immediately following the specified node.

NOTES:

Interrupts are disabled during the insert to ensure the atomicity of the operation.

Use `rtems_chain_insert_unprotected()` to avoid disabling of interrupts.

29.4.16 Append a Node

CALLING SEQUENCE:

```
void rtems_chain_append(  
    rtems_chain_control *the_chain,  
    rtems_chain_node    *the_node  
);
```

RETURNS

Returns nothing.

DESCRIPTION:

This routine appends a node to the end of a chain.

NOTES:

Interrupts are disabled during the append to ensure the atomicity of the operation.

Use `rtems_chain_append_unprotected()` to avoid disabling of interrupts.

29.4.17 Prepend a Node

CALLING SEQUENCE:

```
void rtems_chain_prepend(  
    rtems_chain_control *the_chain,  
    rtems_chain_node    *the_node  
);
```

RETURNS

Returns nothing.

DESCRIPTION:

This routine prepends a node to the front of the chain.

NOTES:

Interrupts are disabled during the prepend to ensure the atomicity of the operation.

Use `rtems_chain_prepend_unprotected()` to avoid disabling of interrupts.

30 Directive Status Codes

RTEMS_SUCCESSFUL - successful completion
RTEMS_TASK_EXITTED - returned from a task
RTEMS_MP_NOT_CONFIGURED - multiprocessing not configured
RTEMS_INVALID_NAME - invalid object name
RTEMS_INVALID_ID - invalid object id
RTEMS_TOO_MANY - too many
RTEMS_TIMEOUT - timed out waiting
RTEMS_OBJECT_WAS_DELETED - object was deleted while waiting
RTEMS_INVALID_SIZE - invalid specified size
RTEMS_INVALID_ADDRESS - invalid address specified
RTEMS_INVALID_NUMBER - number was invalid
RTEMS_NOT_DEFINED - item not initialized
RTEMS_RESOURCE_IN_USE - resources outstanding
RTEMS_UNSATISFIED - request not satisfied
RTEMS_INCORRECT_STATE - task is in wrong state
RTEMS_ALREADY_SUSPENDED - task already in state
RTEMS_ILLEGAL_ON_SELF - illegal for calling task
RTEMS_ILLEGAL_ON_REMOTE_OBJECT - illegal for remote object
RTEMS_CALLED_FROM_ISR - invalid environment
RTEMS_INVALID_PRIORITY - invalid task priority
RTEMS_INVALID_CLOCK - invalid time buffer
RTEMS_INVALID_NODE - invalid node id
RTEMS_NOT_CONFIGURED - directive not configured
RTEMS_NOT_OWNER_OF_RESOURCE - not owner of resource
RTEMS_NOT_IMPLEMENTED - directive not implemented
RTEMS_INTERNAL_ERROR - RTEMS inconsistency detected
RTEMS_NO_MEMORY - could not get enough memory

31 Example Application

```

/*
 * This file contains an example of a simple RTEMS
 * application. It instantiates the RTEMS Configuration
 * Information using confdef.h and contains two tasks:
 * a * user initialization task and a simple task.
 *
 * This example assumes that a board support package exists.
 */

#include <rtems.h>

rtems_task user_application(rtems_task_argument argument);

rtems_task init_task(
    rtems_task_argument ignored
)
{
    rtems_id      tid;
    rtems_status_code status;
    rtems_name     name;

    name = rtems_build_name( 'A', 'P', 'P', '1' );

    status = rtems_task_create(
        name, 1, RTEMS_MINIMUM_STACK_SIZE,
        RTEMS_NO_PREEMPT, RTEMS_FLOATING_POINT, &tid
    );
    if ( status != RTEMS_STATUS_SUCCESSFUL ) {
        printf( "rtems_task_create failed with status of %d.\n", status );
        exit( 1 );
    }

    status = rtems_task_start( tid, user_application, 0 );
    if ( status != RTEMS_STATUS_SUCCESSFUL ) {
        printf( "rtems_task_start failed with status of %d.\n", status );
        exit( 1 );
    }

    status = rtems_task_delete( SELF );    /* should not return */
    printf( "rtems_task_delete returned with status of %d.\n", status );
    exit( 1 );

32 Glossary

active	A term used to describe an object which has been created by an application.
aperiodic task	A task which must execute only at irregular intervals and has only a soft deadline.
application	In this document, software which makes use of RTEMS.
ASR	see Asynchronous Signal Routine.
asynchronous	Not related in order or timing to other occurrences in the system.
Asynchronous Signal Routine	Similar to a hardware interrupt except that it is associated with a task and is run in the context of a task. The directives provided by the signal manager are used to service signals.
awakened	A term used to describe a task that has been unblocked and may be scheduled to the CPU.
big endian	A data representation scheme in which the bytes composing a numeric value are arranged such that the most significant byte is at the lowest address.
bit-mapped	A data encoding scheme in which each bit in a variable is used to represent something different. This makes for compact data representation.
block	A physically contiguous area of memory.
blocked	The task state entered by a task which has been previously started and cannot continue execution until the reason for waiting has been satisfied.
broadcast	To simultaneously send a message to a logical set of destinations.
BSP	see Board Support Package.
Board Support Package	A collection of device initialization and control routines specific to a particular type of board or collection of boards.
buffer	A fixed length block of memory allocated from a partition.
calling convention	The processor and compiler dependent rules which define the mechanism used to invoke subroutines in a high-level language. These rules define the passing of arguments, the call and return mechanism, and the register set which must be preserved.
Central Processing Unit	This term is equivalent to the terms processor and microprocessor.
chain	A data structure which allows for efficient dynamic addition and removal of elements. It differs from an array in that it is not limited to a predefined size.

coalesce	The process of merging adjacent holes into a single larger hole. Sometimes this process is referred to as garbage collection.
Configuration Table	A table which contains information used to tailor RTEMS for a particular application.
context	All of the processor registers and operating system data structures associated with a task.
context switch	Alternate term for task switch. Taking control of the processor from one task and transferring it to another task.
control block	A data structure used by the executive to define and control an object.
core	When used in this manual, this term refers to the internal executive utility functions. In the interest of application portability, the core of the executive should not be used directly by applications.
CPU	An acronym for Central Processing Unit.
critical section	A section of code which must be executed indivisibly.
CRT	An acronym for Cathode Ray Tube. Normally used in reference to the man-machine interface.
deadline	A fixed time limit by which a task must have completed a set of actions. Beyond this point, the results are of reduced value and may even be considered useless or harmful.
device	A peripheral used by the application that requires special operation software. See also device driver.
device driver	Control software for special peripheral devices used by the application.
directives	RTEMS' provided routines that provide support mechanisms for real-time applications.
dispatch	The act of loading a task's context onto the CPU and transferring control of the CPU to that task.
dormant	The state entered by a task after it is created and before it has been started.
Device Driver Table	A table which contains the entry points for each of the configured device drivers.
dual-ported	A term used to describe memory which can be accessed at two different addresses.
embedded	An application that is delivered as a hidden part of a larger system. For example, the software in a fuel-injection control system is an embedded application found in many late-model automobiles.
envelope	A buffer provided by the MPC1 layer to RTEMS which is used to pass messages between nodes in a multiprocessor system. It typically

	contains routing information needed by the MPCl. The contents of an envelope are referred to as a packet.
entry point	The address at which a function or task begins to execute. In C, the entry point of a function is the function's name.
events	A method for task communication and synchronization. The directives provided by the event manager are used to service events.
exception	A synonym for interrupt.
executing	The task state entered by a task after it has been given control of the CPU.
executive	In this document, this term is used to referred to RTEMS. Commonly, an executive is a small real-time operating system used in embedded systems.
exported	An object known by all nodes in a multiprocessor system. An object created with the GLOBAL attribute will be exported.
external address	The address used to access dual-ported memory by all the nodes in a system which do not own the memory.
FIFO	An acronym for First In First Out.
First In First Out	A discipline for manipulating entries in a data structure.
floating point coprocessor	A component used in computer systems to enhance performance in mathematically intensive situations. It is typically viewed as a logical extension of the primary processor.
freed	A resource that has been released by the application to RTEMS.
global	An object that has been created with the GLOBAL attribute and exported to all nodes in a multiprocessor system.
handler	The equivalent of a manager, except that it is internal to RTEMS and forms part of the core. A handler is a collection of routines which provide a related set of functions. For example, there is a handler used by RTEMS to manage all objects.
hard real-time system	A real-time system in which a missed deadline causes the worked performed to have no value or to result in a catastrophic effect on the integrity of the system.
heap	A data structure used to dynamically allocate and deallocate variable sized blocks of memory.
heterogeneous	A multiprocessor computer system composed of dissimilar processors.
homogeneous	A multiprocessor computer system composed of a single type of processor.

ID	An RTEMS assigned identification tag used to access an active object.
IDLE task	A special low priority task which assumes control of the CPU when no other task is able to execute.
interface	A specification of the methodology used to connect multiple independent subsystems.
internal address	The address used to access dual-ported memory by the node which owns the memory.
interrupt	A hardware facility that causes the CPU to suspend execution, save its status, and transfer control to a specific location.
interrupt level	A mask used to by the CPU to determine which pending interrupts should be serviced. If a pending interrupt is below the current interrupt level, then the CPU does not recognize that interrupt.
Interrupt Service Routine	An ISR is invoked by the CPU to process a pending interrupt.
I/O	An acronym for Input/Output.
ISR	An acronym for Interrupt Service Routine.
kernel	In this document, this term is used as a synonym for executive.
list	A data structure which allows for dynamic addition and removal of entries. It is not statically limited to a particular size.
little endian	A data representation scheme in which the bytes composing a numeric value are arranged such that the least significant byte is at the lowest address.
local	An object which was created with the LOCAL attribute and is accessible only on the node it was created and resides upon. In a single processor configuration, all objects are local.
local operation	The manipulation of an object which resides on the same node as the calling task.
logical address	An address used by an application. In a system without memory management, logical addresses will equal physical addresses.
loosely-coupled	A multiprocessor configuration where shared memory is not used for communication.
major number	The index of a device driver in the Device Driver Table.
manager	A group of related RTEMS' directives which provide access and control over resources.
memory pool	Used interchangeably with heap.
message	A sixteen byte entity used to communicate between tasks. Messages are sent to message queues and stored in message buffers.

message buffer	A block of memory used to store messages.
message queue	An RTEMS object used to synchronize and communicate between tasks by transporting messages between sending and receiving tasks.
Message Queue Control Block	A data structure associated with each message queue used by RTEMS to manage that message queue.
minor number	A numeric value passed to a device driver, the exact usage of which is driver dependent.
mode	An entry in a task's control block that is used to determine if the task allows preemption, timeslicing, processing of signals, and the interrupt disable level used by the task.
MPCI	An acronym for Multiprocessor Communications Interface Layer.
multiprocessing	The simultaneous execution of two or more processes by a multiple processor computer system.
multiprocessor	A computer with multiple CPUs available for executing applications.
Multiprocessor Communications Interface Layer	A set of user-provided routines which enable the nodes in a multiprocessor system to communicate with one another.
Multiprocessor Configuration Table	The data structure defining the characteristics of the multiprocessor target system with which RTEMS will communicate.
multitasking	The alternation of execution amongst a group of processes on a single CPU. A scheduling algorithm is used to determine which process executes at which time.
mutual exclusion	A term used to describe the act of preventing other tasks from accessing a resource simultaneously.
nested	A term used to describe an ASR that occurs during another ASR or an ISR that occurs during another ISR.
node	A term used to reference a processor running RTEMS in a multiprocessor system.
non-existent	The state occupied by an uncreated or deleted task.
numeric coprocessor	A component used in computer systems to enhance performance in mathematically intensive situations. It is typically viewed as a logical extension of the primary processor.
object	In this document, this term is used to refer collectively to tasks, timers, message queues, partitions, regions, semaphores, ports, and rate monotonic periods. All RTEMS objects have IDs and user-assigned names.
object-oriented	A term used to describe systems with common mechanisms for utilizing a variety of entities. Object-oriented systems shield the application from implementation details.

operating system	The software which controls all the computer's resources and provides the base upon which application programs can be written.
overhead	The portion of the CPUs processing power consumed by the operating system.
packet	A buffer which contains the messages passed between nodes in a multiprocessor system. A packet is the contents of an envelope.
partition	An RTEMS object which is used to allocate and deallocate fixed size blocks of memory from an dynamically specified area of memory.
Partition Control Block	A data structure associated with each partition used by RTEMS to manage that partition.
pending	A term used to describe a task blocked waiting for an event, message, semaphore, or signal.
periodic task	A task which must execute at regular intervals and comply with a hard deadline.
physical address	The actual hardware address of a resource.
poll	A mechanism used to determine if an event has occurred by periodically checking for a particular status. Typical events include arrival of data, completion of an action, and errors.
pool	A collection from which resources are allocated.
portability	A term used to describe the ease with which software can be rehosted on another computer.
posting	The act of sending an event, message, semaphore, or signal to a task.
preempt	The act of forcing a task to relinquish the processor and dispatching to another task.
priority	A mechanism used to represent the relative importance of an element in a set of items. RTEMS uses priority to determine which task should execute.
priority inheritance	An algorithm that calls for the lower priority task holding a resource to have its priority increased to that of the highest priority task blocked waiting for that resource. This avoids the problem of priority inversion.
priority inversion	A form of indefinite postponement which occurs when a high priority tasks requests access to shared resource currently allocated to low priority task. The high priority task must block until the low priority task releases the resource.
processor utilization	The percentage of processor time used by a task or a set of tasks.
proxy	An RTEMS control structure used to represent, on a remote node, a task which must block as part of a remote operation.

Proxy Control Block	A data structure associated with each proxy used by RTEMS to manage that proxy.
PTCB	An acronym for Partition Control Block.
PXCB	An acronym for Proxy Control Block.
quantum	The application defined unit of time in which the processor is allocated.
queue	Alternate term for message queue.
QCB	An acronym for Message Queue Control Block.
ready	A task occupies this state when it is available to be given control of the CPU.
real-time	A term used to describe systems which are characterized by requiring deterministic response times to external stimuli. The external stimuli require that the response occur at a precise time or the response is incorrect.
reentrant	A term used to describe routines which do not modify themselves or global variables.
region	An RTEMS object which is used to allocate and deallocate variable size blocks of memory from a dynamically specified area of memory.
Region Control Block	A data structure associated with each region used by RTEMS to manage that region.
registers	Registers are locations physically located within a component, typically used for device control or general purpose storage.
remote	Any object that does not reside on the local node.
remote operation	The manipulation of an object which does not reside on the same node as the calling task.
return code	Also known as error code or return value.
resource	A hardware or software entity to which access must be controlled.
resume	Removing a task from the suspend state. If the task's state is ready following a call to the <code>rtems_task_resume</code> directive, then the task is available for scheduling.
return code	A value returned by RTEMS directives to indicate the completion status of the directive.
RNCB	An acronym for Region Control Block.
round-robin	A task scheduling discipline in which tasks of equal priority are executed in the order in which they are made ready.
RS-232	A standard for serial communications.

running	The state of a rate monotonic timer while it is being used to delineate a period. The timer exits this state by either expiring or being canceled.
schedule	The process of choosing which task should next enter the executing state.
schedulable	A set of tasks which can be guaranteed to meet their deadlines based upon a specific scheduling algorithm.
segments	Variable sized memory blocks allocated from a region.
semaphore	An RTEMS object which is used to synchronize tasks and provide mutually exclusive access to resources.
Semaphore Control Block	A data structure associated with each semaphore used by RTEMS to manage that semaphore.
shared memory	Memory which is accessible by multiple nodes in a multiprocessor system.
signal	An RTEMS provided mechanism to communicate asynchronously with a task. Upon reception of a signal, the ASR of the receiving task will be invoked.
signal set	A thirty-two bit entity which is used to represent a task's collection of pending signals and the signals sent to a task.
SMCB	An acronym for Semaphore Control Block.
soft real-time system	A real-time system in which a missed deadline does not compromise the integrity of the system.
sporadic task	A task which executes at irregular intervals and must comply with a hard deadline. A minimum period of time between successive iterations of the task can be guaranteed.
stack	A data structure that is managed using a Last In First Out (LIFO) discipline. Each task has a stack associated with it which is used to store return information and local variables.
status code	Also known as error code or return value.
suspend	A term used to describe a task that is not competing for the CPU because it has had a <code>rtems_task_suspend</code> directive.
synchronous	Related in order or timing to other occurrences in the system.
system call	In this document, this is used as an alternate term for directive.
target	The system on which the application will ultimately execute.
task	A logically complete thread of execution. The CPU is allocated among the ready tasks.
Task Control Block	A data structure associated with each task used by RTEMS to manage that task.

task switch	Alternate terminology for context switch. Taking control of the processor from one task and given to another.
TCB	An acronym for Task Control Block.
tick	The basic unit of time used by RTEMS. It is a user-configurable number of microseconds. The current tick expires when the <code>rtems_clock_tick</code> directive is invoked.
tightly-coupled	A multiprocessor configuration system which communicates via shared memory.
timeout	An argument provided to a number of directives which determines the maximum length of time an application task is willing to wait to acquire the resource if it is not immediately available.
timer	An RTEMS object used to invoke subprograms at a later time.
Timer Control Block	A data structure associated with each timer used by RTEMS to manage that timer.
timeslicing	A task scheduling discipline in which tasks of equal priority are executed for a specific period of time before being preempted by another task.
timeslice	The application defined unit of time in which the processor is allocated.
TMCB	An acronym for Timer Control Block.
transient overload	A temporary rise in system activity which may cause deadlines to be missed. Rate Monotonic Scheduling can be used to determine if all deadlines will be met under transient overload.
user extensions	Software routines provided by the application to enhance the functionality of RTEMS.
User Extension Table	A table which contains the entry points for each user extensions.
User Initialization Tasks Table	A table which contains the information needed to create and start each of the user initialization tasks.
user-provided	Alternate term for user-supplied. This term is used to designate any software routines which must be written by the application designer.
user-supplied	Alternate term for user-provided. This term is used to designate any software routines which must be written by the application designer.
vector	Memory pointers used by the processor to fetch the address of routines which will handle various exceptions and interrupts.
wait queue	The list of tasks blocked pending the release of a particular resource. Message queues, regions, and semaphores have a wait queue associated with them.
yield	When a task voluntarily releases control of the processor.

Concept Index

A

add memory to a region	158
announce arrival of package	282
announce fatal error	189
aperiodic task, definition	198
ASR	137
ASR mode, building	138
ASR vs. ISR	137
asynchronous signal routine	137

B

barrier	219
binary semaphores	101
Board Support Packages	227
broadcast message to a queue	125
BSP, definition	227
BSPs	227
buffers, definition	143
build object id from components	312
build object name	304

C

cancel a period	211
cancel a timer	92
chain append a node	340
chain extract a node	337
chain get first node	338
chain get head	328
chain get tail	329
chain initialize	325
chain initialize empty	326
chain insert a node	339
chain is chain empty	331
chain is node null	327
chain is node the first	332
chain is node the head	335
chain is node the last	333
chain is node the tail	336
chain iterate	323
chain only one node	334
chains	321
chare are nodes equal	330
clock	73
clock get uptime	83
clock set nanoseconds extension	84
clock tick	85
close a device	183
communication and synchronization	18
conclude current period	213
confdefs.h	243
Configuration Table	253
convert external to internal address	170

convert internal to external address	171
counting semaphores	101
CPU Dependent Information Table	263
create a barrier	222
create a message queue	119
create a partition	145
create a period	209
create a port	167
create a region	155
create a semaphore	107
create a task	42
create a timer	90
create an extension set	240
current task mode	53
current task priority	52

D

delay a task for an interval	56
delay a task until a wall time	57
delays	74
delete a barrier	224
delete a message queue	122
delete a partition	148
delete a period	212
delete a port	169
delete a region	157
delete a semaphore	110
delete a timer	93
delete an extension set	242
deleting a task	48
device driver interface	175
Device Driver Table	173, 264
device drivers	173
device names	174
disable interrupts	68
disabling interrupts	64
dispatching	192
dual ported memory	165
dual ported memory, definition	165

E

enable interrupts	69
establish an ASR	140
establish an ISR	67
event condition, building	131
event flag, definition	131
event set, building	131
event set, definition	131
events	131
extension set	233
external addresses, definition	165

F

fatal error detection	187
fatal error processing	187
fatal error user extension	187
fatal error, announce	189
fatal errors	187
fire a task-based timer at wall time	98
fire a timer after an interval	94
fire a timer at wall time	95
fire task-based a timer after an interval	97
flash interrupts	70
floating point	36
flush a semaphore	114
flush messages on a queue	129

G

get buffer from partition	149
get class from object ID	17
get ID of a barrier	223
get ID of a message queue	121
get ID of a partition	147
get ID of a period	210
get ID of a port	168
get ID of a region	156
get ID of a semaphore	109
get ID of a task	44
get ID of an extension set	241
get index from object ID	17
get name from id	305
get node from object ID	17
get number of pending messages	128
get object name as string	306
get per-task variable	60
get segment from region	159
get size of segment	162
get statistics of period	215
get status of period	214
get task mode	53
get task notepad entry	54
get task preemption mode	53
get task priority	52
global objects table	276
global objects, definition	276

H

heterogeneous multiprocessing	280
-------------------------------------	-----

I

initialization tasks	25
Initialization Tasks Table	263
initialize a device driver	179
initialize device drivers	30
initialize RTEMS	31
initialize RTEMS before device drivers	29

initialize RTEMS data structures	28
initiate the Timer Server	96
install an ASR	140
install an ISR	67
internal addresses, definition	165
interrupt level, task	35
interrupt levels	64
interrupt processing	63
IO Control	186
IO Manager	173
is interrupt in progress	71
is task suspended	51
ISR vs. ASR	137
iterate over all threads	58

L

libpci	283
lock a barrier	225
lock a semaphore	111
lookup device major and minor number	181

M

major device number	174
manual round robin	192
memory management	19
message queue attributes	115
message queues	115
messages	115
minor device number	174
MPCI and remote operations	276
MPCI entry points	278
MPCI, definition	278
multiprocessing	275
multiprocessing topologies	275
Multiprocessor Communications Interface Table	269
Multiprocessor Configuration Table	267
mutual exclusion	101

N

nanoseconds extension	84
nanoseconds time accuracy	84
nodes, definition	275

O

object ID	16
object ID composition	16
object manipulation	301
object name	15
objects	15
obtain a barrier	225
obtain a semaphore	111
obtain API from id	308
obtain API name	317

obtain buffer from partition.....	149
obtain class from object id.....	309
obtain class information.....	319
obtain class name.....	318
obtain ID of a barrier.....	223
obtain ID of a partition.....	147
obtain ID of a period.....	210
obtain ID of a port.....	168
obtain ID of a region.....	156
obtain ID of a semaphore.....	109
obtain ID of an extension set.....	241
obtain ID of caller.....	45
obtain index from object id.....	311
obtain maximum API value.....	314
obtain maximum class value.....	316
obtain minimum API value.....	313
obtain minimum class value.....	315
obtain name from id.....	305
obtain node from object id.....	310
obtain object name as string.....	306
obtain per-task variable.....	60
obtain seconds since epoch.....	80, 81
obtain statistics of period.....	215
obtain status of period.....	214
obtain task mode.....	53
obtain task priority.....	52
obtain the ID of a timer.....	91
obtain the time of day.....	77, 78, 79
obtain ticks since boot.....	82
obtaining class from object ID.....	17
obtaining index from object ID.....	17
obtaining node from object ID.....	17
open a device.....	182

P

partition attribute set, building.....	143
partition, definition.....	143
partitions.....	143
per task variables.....	37
per-task variable.....	59, 61
period initiation.....	213
period statistics report.....	218
periodic task, definition.....	198
periodic tasks.....	197
ports.....	165
POSIX API Configuration Table.....	260
preemption.....	35, 192
prepend node.....	341
print period statistics report.....	218
priority, task.....	34
proxy, definition.....	277
put message at front of queue.....	124

R

rate mononitonic tasks.....	197
-----------------------------	-----

Rate Monotonic Scheduling Algorithm, definition.....	199
read from a device.....	184
receive event condition.....	135
receive message from a queue.....	126
region attribute set, building.....	151
region, add memory.....	158
region, definition.....	151
regions.....	151
register a device driver.....	177
register device.....	180
release a barrier.....	226
release a semaphore.....	113
reset a timer.....	99
reset statistics of all periods.....	217
reset statistics of period.....	216
resize segment.....	163
restarting a task.....	47
resuming a task.....	50
return buffer to partition.....	150
return segment to region.....	161
RMS Algorithm, definition.....	199
RMS First Deadline Rule.....	201
RMS Processor Utilization Rule.....	200
RMS schedulability analysis.....	200
round robin scheduling.....	192
RTEMS API Configuration Table.....	257
RTEMS Configuration Table.....	253
runtime driver registration.....	174

S

scheduling.....	191
scheduling mechanisms.....	191
segment, definition.....	151
semaphores.....	101
send event set to a task.....	134
send message to a queue.....	123
send signal set.....	141
set object name.....	307
set task mode.....	53
set task notepad entry.....	55
set task preemption mode.....	53
set task priority.....	52
set the time of day.....	76
shutdown RTEMS.....	32
signal set, building.....	137
signals.....	137
special device services.....	186
sporadic task, definition.....	198
start current period.....	213
start multitasking.....	31
starting a task.....	46
suspending a task.....	49

T

task arguments.....	36
---------------------	----

task attributes, building	37
task mode	35
task mode, building	38
task priority	34, 191
task private data	59, 61
task private variable	59, 61
task prototype	36
task scheduling	191
task state transitions	193
task states	34
task, definition	33
tasks	33
TCB extension area	234
time	18
timeouts	74
timers	87
timeslicing	35, 74, 192

U

unblock all tasks waiting on a semaphore	114
unlock a semaphore	113
unregister a device driver	178
uptime	83
user extensions	233
User Extensions Table	265

W

wait at a barrier	226
wake up after an interval	56
wake up at a wall time	57
write to a device	185
